INSTRUCTIONS

Optional Form 272, Report Documentation Page is based on Guidelines for Format and Production of Scientific and Technical Reports, ANSI Z39.18–1974 available from American National Standards Institute, 1430 Broadway, New York, New York 10018. Each separately bound report—for example, each volume in a multivolume set—shall have its unique Report Documentation Page.

- 1. Report Number. Each individually bound report shall carry a unique alphanumeric designation assigned by the performing organization or provided by the sponsoring organization in accordance with American National Standard ANSI Z39.23–1974, Technical Report Number (STRN). For registration of report code, contact NTIS Report Number Clearinghouse, Springfield, VA 22161. Use uppercase letters, Arabic numerals, slashes, and hyphens only, as in the following examples: FASEB/NS-75/87 and FAA/RD-75/09.
- 2. Leave blank.
- 3. Recipient's Accession Number. Reserved for use by each report recipient.
- 4. Title and Subtitle. Title should indicate clearly and briefly the subject coverage of the report, subordinate subtitle to the main title. When a report is prepared in more than one volume, repeat the primary title, add volume number and include subtitle for the specific volume.
- 5. Report Date. Each report shall carry a date indicating at least month and year. Indicate the basis on which it was selected (e.g., date of issue, date of approval, date of preparation, date published).
- 6. Sponsoring Agency Code. Leave blank.
- 7. Author(s). Give name(s) in conventional order (e.g., John R. Doe, or J. numert Doe). List author's affiliation if it differs from the performing organization.
- 8. Performing Organization Report Number. Insert if performing organization wishes to assign this number.
- 9. Performing Organization Name and Mailing Address. Give name, street, city, state, and ZIP code. List no more than two levels of an organizational hierarchy. Display the name of the organization exactly as it should appear in Government indexes such as Government Reports Announcements & Index (GRA & I).
- 10. Project/Task/Work Unit Number. Use the project, task and work unit numbers under which the report was prepared.
- 11. Contract/Grant Number. Insert contract or grant number under which report was prepared.
- 12. Sponsoring Agency Name and Mailing Address. Include ZIP code. Cite main sponsors.
- 13. Type of Report and Period Covered. State interim, final, etc., and, if applicable, inclusive dates.
- 14. Performing Organization Code. Leave blank.
- 15. Supplementary Notes. Enter information not included elsewhere but useful, such as: Prepared in cooperation with . . . Translation of . . . Presented at conference of . . . To be published in . . . When a report is revised, include a statement whether the new report supersedes or supplements the older report.
- 16. Abstract. Include a brief (200 words or less) factual summary of the most significant information contained in the report. If the report contains a significant bibliography or literature survey, mention it here.
- 17. Document Analysis. (a). Descriptors. Select from the Thesaurus of Engineering and Scientific Terms the proper authorized terms that identify the major concept of the research and are sufficiently specific and precise to be used as index entries for cataloging.
 - (b). Identifiers and Open-Ended Terms. Use identifiers for project names, code names, equipment designators, etc. Use open-ended terms written in descriptor form for those subjects for which no descriptor exists.
 - (c). COSATI Field/Group. Field and Group assignments are to be taken from the 1964 COSATI Subject Category List. Since the majority of documents are multidisciplinary in nature, the primary Field/Group assignment(s) will be the specific discipline, area of human endeavor, or type of physical object. The application(s) will be cross-referenced with secondary Field/Group assignments that will follow the primary posting(s).
- 18. Distribution Statement. Denote public releasability, for example "Release unlimited", or limitation for reasons other than security. Cite any availability to the public, with address, order number and price, if known.
- 19. 4 20. Security Classification. Enter U.S. Security Classification in accordance with U.S. Security Regulations (i.e., UNCLASSIFIED).
- 21. Number of pages. Insert the total number of pages, including introductory pages, but excluding distribution list, if any.
- 22. Price. Enter price in paper copy (PC) and/or microfiche (MF) if known.

User's Manual

Chapter 1

Introduction

When siting antennas on large structures, it is desirable to be able to quickly determine the clear line of sight transmission or reception paths for the antennas. If the structure under consideration is a space station, there will be many antennas to consider in an environment composed of a very large and complex array of living and working module, solar panels, and support structures. The antennas will potentially need to communicate with systems anywhere around the near zone of the structure and the complete far zone sphere. In short, a challenging problem.

In order to aid the antenna design engineer in the prediction of the near and far zone antenna patterns, antenna to antenna coupling, and radiation hazard considerations, for high frequency antennas in a complex environment, a couple of user oriented computer codes have been developed: the NEC - Basic Scattering Code (NEC-BSC) [1,2] and the Aircraft Code (NEWAIR) [3]. Both codes are based on the Uniform Geometrical Theory of Diffraction (UTD) [4], which is a high frequency ray optical method with corrections at shadow boundaries. The UTD is ideal for construction of efficient computer codes, such as these, for modeling the scattering from large structures. The NEC-BSC and NEWAIR are complementary codes, that is, the NEC-BSC is used when the antennas are not mounted on a curved surface, and the NEWAIR is used when the antennas are mounted on a curved surface. Both codes use plates to model flat structures, the NEC-BSC presently uses finite elliptic cylinders to model curved surfaces, and the NEWAIR presently uses ellipsoids.

Although the two UTD codes are presently very useful for predicting the performance of antennas in a complex environment, such as a space station, there are a few important consideration that should be taken into account. First, the present versions of these codes were not specifically developed for a space station application. The NEC-BSC was developed for ships and the NEWAIR for aircraft. Second and most importantly, even though they run fast for large size structures in terms of a wavelength, as compared with computer codes using other theories, such as method of moments; a problem with as many structural pieces as a space station can take a very long time to calculate a volumetric pattern. This means that the problem of antenna siting in a large structural environment should be viewed as a multiple stepped procedure to optimize results for minimum time and cost.

The design procedure for antenna siting can be viewed as a three step process, as far as the computer codes are concerned. First, it can generally be assumed that a good antenna location will provide a clear line of sight path between transmitter and receiver over the desired range of operation. This can best be accomplished using a obscuration code, which

is the goal of this computer code and document. This code will provide a volumetric shadow map of the projected shadow of a structure onto the far zone sphere centered at the antenna location. It is very fast running on space station applications and can be run interactively providing nearly immediate answers depending on the overall useage of the computer.

Second, a worst case code could be developed that will predict not only the clear line of sight regions, but will also map out the maximum values of the various field terms, such as the reflected and diffracted lobes. These scattered fields can cause undesired lobes to show up in the region of interest. This type of code will not only provide an answer to the question of where the optimum location for an antenna system should be, but also how it should be oriented at that position and what the gain and side lobe levels would be optimum. It can be designed to run at a little additional time cost over the obscuration code.

The final step would be to run a field prediction code such as the NEC-BSC and NEWAIR codes or their future versions optimized for the space station. This would be the confirmation phase of the design procedure to make sure that no surprises occur in the volumetric patterns. At this stage, it does not matter that the codes take a little longer to run, especially for the wealth of information that they produce. Of course, these results can be used to compare with measured results on scale models to validate the measurements and vice versa.

This document is concerned with the obscuration code, referred to here as "SHADOW". It has been specifically design with space station applications in mind. It directly solves for a shadow map by projecting the border of multiple sided flat plates and composite cone frustums of elliptic cross section onto the far zone sphere. It then fills between the borders based on a pixel resolution and window size specified by the user. The definition of the geometry is based on a subset of the command word input system used for the UTD codes. This means that as the engineer proceeds through a design scenario progressing through the different levels of codes, there will be a minimum amount of conversion of input information.

The obscuration code has proven to be so efficient, that it was felt that it could be of great benefit to the design engineer to be able to run it in an interactive mode. Unfortunately, interactive procedures are not generally transportable between different computer systems. Because of the wide availablity of DEC VAX computers in the engineering environment, and because of the ease of developing an interactive system on a VAX, the interactive features have been developed using devise dependent software for the VAX. The non-interactive and interactive parts of the code have been kept separate, however, so that the code can be run non-interactively without much change.

This document is divided into two parts. Part I is a user manual, that treats the code more or less as a black box device. It is about all that will be need for the average user to get started and obtain results. Chapter 2 describes the method that is used to obtain the shadow. The overall view of the operation of the code is given in Chapter 3. It describes the non-interactive and interactive commands in a qualitative way. A dictionary of all the non-interactive commands needed in the SHADOW code is given in Chapter 4. It gives the details for inputting each command. Chapter 5 provides the details for the interactive commands. The output features are interpreted in Chapter 6. Examples on how to use the code are given in Chapter 7. When first learning how to use the code, it is essential to be able to reproduce some of these examples to be sure that the code is functioning properly

on your system.

Part II of this document is a code manual. It goes into more specific information about the coding itself. It is of importance primarily for people implementing the code on a new system, for debugging errors, or for making changes in how the code operates. An overview of how the code is organized is given in Chapter 9. A listing of the code is given in Chapter 10. It is broken up into three parts for the non-interactive, FORTRAN 77 subroutines and into the interactive VAX dependent subroutines. The implementation of the code on a VAX is given in Chapter 11 and a brief description of implementing the code on a non-VAX computer is given in Chapter 12. A listing of an NCAR plotting code for the shadow map is given in Chapter 13.

Chapter 2

Method

The first gauge of the ability of two antenna systems to communicate with one another at high frequencies is to determine if there is a clear line of sight path between them. This can be conveniently represented by a map of the projected shadow on the far zone sphere caused by the structures around an antenna's environment. One method of producing a shadow map is to choose an observation point on the far zone sphere and then determine if anything obscures the path and then move on to the next point. This method is slow, however, because there must be many repeated tests on the same blocking structures for the various observation point making up the shadow map.

In order to have quick turn around for antennas mounted on large structures, it is desirable to use a method that will directly produce the shadow projected onto the far zone sphere. This can be accomplished in a two step process. First the outside boundary of each individual piece making up the structure can be transformed from the x, y, z coordinate system into a sequence of lines in the θ and ϕ pattern coordinate system. The area of the shadow map between the boundary lines for each piece may then be filled by looking at the center location between the lines and a shadow check on that piece of the structure can be performed. This reduces the test on each piece of structure from once every observation point to a few tests every pattern cut line. The calculation time, in general, is reduced by about two orders of magnitude. For example, instead of taking two hours, a map can conservatively be produced in about one minutes or better. These numbers dependent on the geometry, the window size of the map, and the resolution desired.

There are two fundamental types of structural pieces presently available for modeling in this obscuration code, the multiple sided flat plate and the multiple rimmed composite cone frustum of elliptic cross section. More than one plate or cylinder can be specified to build up a complex structure. A plate can be defined by the location of its corners in a reference coordinate system. A cone frustum can be defined by the size of its major and minor radii for each rim making up the composite cylinder.

The boundary of the structures are traced onto the far zone sphere by defining a vector from the source position, \bar{R}_s , to some position along its outer boundary, \bar{R}_i , such that

$$\bar{R} = \bar{R}_i - \bar{R}_s.$$

In the case of the plate, the boundary is defined by some location along its edges, as illustrated in Figure 2.1. This vector can then be transformed into the pattern cut coordinate system, since the pattern may be defined relative to a different set of axes. The vector can

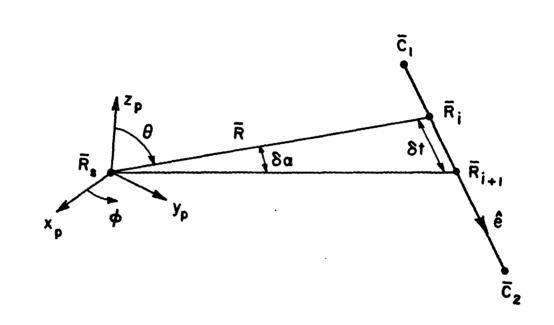

Figure 2.1: Geometry showing the projection of the plate edge onto the far zone sphere.

then be transformed onto the two dimensional far zone sphere by

$$\theta = \arctan\left(\hat{\rho} \cdot \bar{R}/\hat{z} \cdot \bar{R}\right)$$

and

$$\phi = \arctan\left(\hat{y}\cdot\bar{R}/\hat{x}\cdot\bar{R}\right)$$
.

The position of the vector along the edge is defined by starting at a corner and then incrementing the edge in steps of δt along the edge. In order to provide the most efficient performance and the best image of the shadow on the map, it is necessary to define δt as a function of the chosen resolution desired for the map, $\delta \alpha$, the distance, R, from the source to the edge point and the relative position of the projected shadow point with respect to the polar caps, the Greenland effect.

The resolution, $\delta \alpha$ is chosen to be the minimum of the two specified incremental values of θ and ϕ . The distance R is defined as $R = |\bar{R}_s - \bar{R}_i|$. Assuming that the resolution increment is small and the distance is relatively large, the value of the edge increment is given by

$$\delta t = \delta \alpha R \sin \theta.$$

The new edge point then becomes

$$\bar{R}_{i+1} = \bar{R}_i + \delta t \hat{e},$$

where \hat{e} is the edge vector pointing from the first corner to the second corner making up the edge.

The composite cone frustum can be done in the same way as the plate. In fact the end caps can be defined as plates with curved edges and the curved surfaces are added as edges whose corners are the tangent points illustrated in Figure 2.2.

Once a give plate or cylinder outer boundary is transformed onto the shadow map and stored in pixels of the desired resolution, the fill process can begin. The pixel array is considered one row at a time in a scanning operation from the one range of theta embodied in the pixel array to the other. The direction of the scan and the order in which rows are scanned is arbitrary. The fill process is the same for each scan line in the pixel array so that no logical interaction between lines takes place. The process is similar to the way in which a television paints pictures one row at a time on the screen. As the scan proceeds say from left to right, unlit pixels between object boundaries on the line which correspond to regions in the interior of the object are turned on creating an area fill. The decision to light a group of pixels on a given row is not made by testing each pixel individually for obscuration but by making a single test between the pixels which represent boundaries of the projected regions. In this way, only a single test is made to determine whether a whole group of pixels represent the interior or exterior of a region. This is one major key to the sizable reduction of processor time achieved.

The shadow test for a plate is made by first projecting the vector chosen at the mid point of the scan line, \hat{r} , onto the plane of the plate to find its intersection point, as shown in Figure 2.3, that is

$$\bar{R}_t = \bar{R}_s - \frac{[\hat{n} \cdot (\bar{R}_s - \bar{C}_1)]\hat{r}}{\hat{n} \cdot \hat{r}}.$$

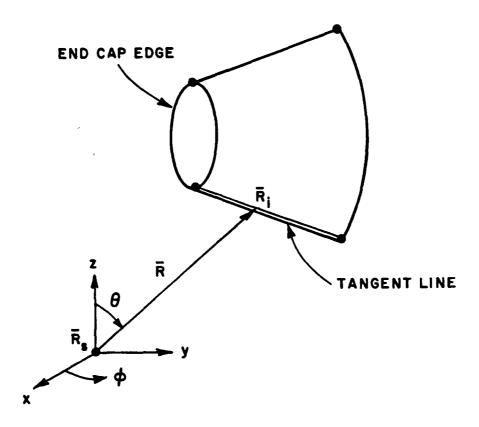

Figure 2.2: Geometry showing the projection of a cone frustum onto the far zone sphere.

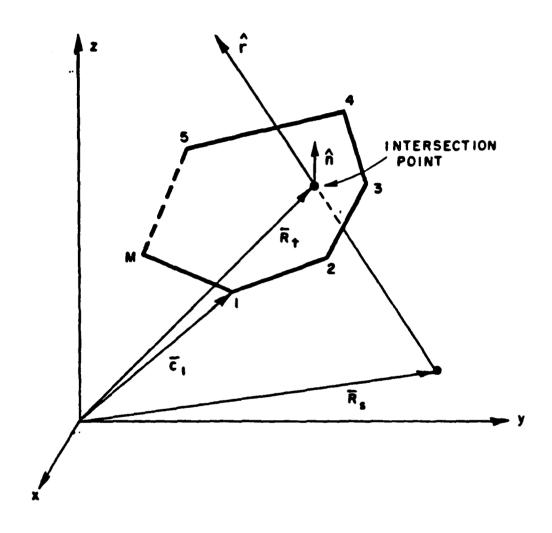

Figure 2.3: Intersection of observation direction vector with plate.

Now, using an idea based on Cauchy's formula from complex variables, that is,

$$\oint_C f(z) dz = \begin{cases} 0, & \text{no pole in } f(z) \\ 2\pi j, & \text{one pole in } f(z) \end{cases}.$$

the intersection point can be tested to see whether or not it falls within the limits of the plate. This is illustrated in Figure 2.4.

It is easy to show that

$$heta_m = \arctan \left[rac{\left[\left(ar{C}_m - ar{R}_t
ight) imes \left(ar{C}_{m+1} - ar{R}_t
ight)
ight] \cdot \hat{n}}{\left(ar{C}_m - ar{R}_t
ight) \cdot \left(ar{C}_{m+1} - ar{R}_t
ight)}
ight]$$

which leads to the test, if

$$\left| \sum_{m=1}^{M} \theta_m \right| = \left\{ \begin{array}{l} <\pi, & \text{no hit occurs} \\ >\pi, & \text{a hit occurs} \end{array} \right.$$

The end caps of the cone frustum cylinders can be done in the same way, by projecting the hit point in the plane of the end cap. The hit point distance can be tested from the center of the disk to see if it falls within the finite limits of a disk to simplify things a little. The curved surface test is a different matter, but still quite easy to accomplish. A vector on the surface of the cone frustum can be represented as

$$\bar{R}_c = \bar{R} + \bar{R}_s$$

01

$$\bar{R}_c = (R\cos\phi\sin\theta + x_s)^2\hat{x} + (R\sin\phi\sin\theta + y_s)^2\hat{y} + (R\cos\theta + z_s)^2\hat{z}.$$

The geometry is illustrated in Figure 2.5. The point defined by R_c should satisfy the equation for a cone, that is,

$$\frac{(R\cos\theta+x_s)^2}{a_j^2}+\frac{(R\sin\phi\sin\theta+y_s)^2}{b_j^2}-\lambda_j^2(R\cos\theta+z_s)=0$$

where

$$\lambda_j(R\cos\theta+z_s)=\left[1+\frac{1}{a_j}\tan\theta_j(R\cos\theta+z_s-z_j)\right].$$

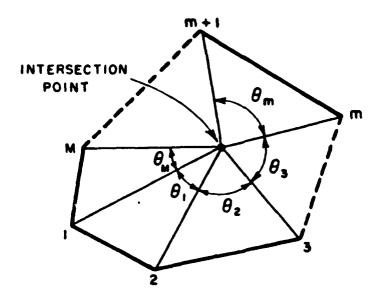

The distance R is unknown in this equation, since we know the direction to the observer, θ and ϕ , but not the distance to the hit point. We can solve for R, however, from the above equations using

$$\alpha R^2 + 2\beta R + \gamma = 0,$$

where

$$\alpha = \frac{\cos^2\phi\sin^2\theta}{a_j^2} + \frac{\sin^2\phi\sin^2\theta}{b_j^2} - \frac{\tan^2\theta_j\cos^2\theta}{a_j^2},$$

$$\beta = \frac{x_s \cos \phi \sin \theta}{a_i^2} + \frac{y_s \sin \phi \sin \theta}{b_i^2} - \tan \theta_j \cos \theta \lambda_j(z_s),$$

(0) RAY HITS PLATE

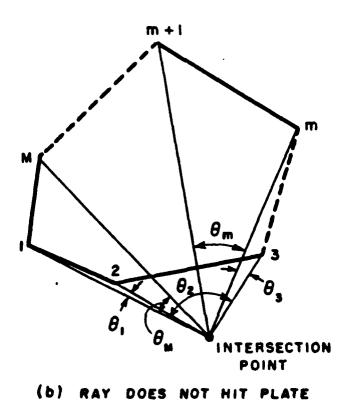

Figure 2.4: The geometry for deciding whether a ray does or does not hit the plate.

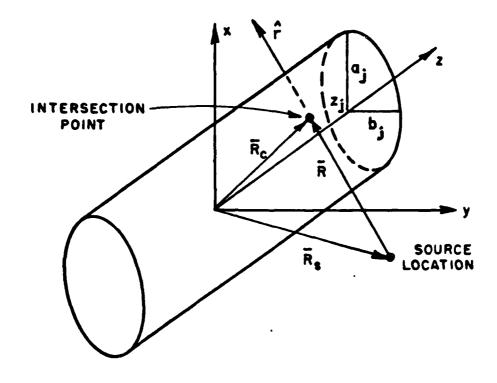

Figure 2.5: Geometry illustrating the hit point on a cone frustum segment.

and

$$\gamma = \frac{x_s^2}{a_j^2} + \frac{y_s^2}{b_j^2} - \lambda_j^2(z_s).$$

If the value of R is real, then the hit point is on the finite cone frustum and therefore the ray from the source to observer is shadowed. If the actual hit point is desired it should be noted that there are two values found from this equation, and that the right hit point can be found from the one representing the shortest distance. If the value of R is imaginary, however, this indicates that the hit point is off the real boundary of the cone frustum and therefore the ray is not shadowed. If R is real, an additional test must be made to decide whether the hit point in between the finite length bounds of the frustum.

The basic theory discussed here is rather straight forward. The implementation, of course, requires a lot of other considerations to be user friendly and as general purpose as possible. The next chapter will go into more detail about how the code interfaces with the operator.

Chapter 3

Principle of Operation

3.1 Overview

The Obscuration Code is intended to be an efficient means of determining the clear line of sight path for an antenna mounted in a complex environment. This code produces a shadow map of the geometry for a given source location. The configuration is defined using a command word system as discussed below. The geometry of the structure is defined by using plates and cylinders. It is thought that the obscuration code is just one step in a total evaluation scheme. The next step would be to either look at a "worst case" map that projects the location of the maximum lobes on to a volumetric map or to calculate the fields using a code like the NEC-BSC. In any case, the real fields should be calculated as the final step whether an intermediate one is used or not. For this reason, the geometry definition is based on the NEC-BSC code method of inputting information.

The obscuration code, however, is a very efficient means of providing a shadow map. It can be run in a matter of minutes or less for a given shadow map. It is, therefore, felt that it can be most efficiently run interactively, that is with the user sitting at a terminal changing antenna locations, looking at the resultant maps, deciding where to try the next antenna location until the desired optimum spot is found to achieve a given performance. For this reason the code has been developed in two pieces. One is a standard FORTRAN 77 part that does the essential shadowing calculations. The second is an interactive part that allows the user to change the source locations and window size without leaving the code. Unfortunately, this second part of the code is by nature device dependent. This part has been written for the DEC VAX series of computers using version 4 of VMS. It uses system handlers for defining the commands discussed in the sections below for the interactive commands and the keypad mode. The keys on the keypad of VT100 or VT200 series terminals can be used to represent the typed commands. This will simplify the use of the code by reducing the amount of typing necessary.

This chapter tries to give a brief overview of the specifics needed to run the code by treating it as a black box. It is intended to just get the user comfortable with the overall philosophy of the obscuration code.

3.2 Modeling the Structures

The building blocks available for the obscuration code are composed of pieces that are an extension of version 2 of the NEC-BSC [1]. Structures can be modeled using multiple sided flat plates and multiple rimmed cone frustum cylinders. The plates can be used individually to model things like solar panels or together to form box like structures to model things like the mast, etc. The cone frustums are a new feature here, and can be handy for modeling living modules, etc. Examples of space station models are given in Chapter 7.

Unlike the NEC-BSC, there are no real restrictions on how these structures are defined. Since the code just looks at each defined piece of the modeled structure individually, casts its shadow, then moves on to the next piece, it does not have to properly account for the wedge angles and other geometrical features needed in field calculations in the NEC-BSC. If one is setting up a model, however, it still might be useful to use the same modeling considerations as the NEC-BSC, such as defining the corners of a plate so the normals point in the region of space in which the source is located. It is assumed that the obscuration code phase of the design procedure will be followed by calculating the fields for the antenna on the structure using a code such as the NEC-BSC.

The number of plates and cylinders that can be used in the models is dictated only by the size of the dimensions implemented in the array for defining the geometry in the code. For convenience, these parameters are located in one file in the code so they only need to be changed in one spot. The details are given in Part II.

More information on how models are to be constructed are given in the section below on the non-interactive commands and in Chapter 4 where these commands are defined in more detail.

3.3 Running the Code

The first step of course is to get the code implemented on your system. The details of how to accomplish this are given in Part II. In order to use the full interactive features of the code, it is necessary to use the code on a DEC VAX. Many of the interactive features use VAX dependent implementations from version 4 of the VMS operating system. The code has been divided into standard FORTRAN 77 files and VAX dependent files, however, so that the code can be used without the interactive features on other systems. A slightly different main program needs to be used as provided in Part II. In addition, the non FORTRAN 77 INCLUDE statement has been used in the non interactive file. Many systems have this feature, so it was left in as a convenience. If the user system does not, it is easy to remove by hard wiring the lines in the appropriate file in place of the INCLUDE statement. Most of the information, here, will assume that the full features of the code will be able to be used.

The first step in using the code is to create a file that contains the basic structure definitions using the non-interactive commands discussed in the next section. The command defining the source location and window size of the shadow map can also be defined in this input file or added and changed in the interactive session. Of course, if you are running non-interactively, then all the data must be input from the input file.

Once the input file has been created or chosen from some stored files, the obscuration

code can be executed. It will read the input file from logical unit #5. An interactive command allows the user to connect the chosen input file to this logical unit number. The code then proceeds to read the input information and produce an output that is sent to the terminal (logical unit #6) representing how the code has interpreted the input. In this process, it is converting all the input into a standard reference coordinate system and into a common set of units which is meters. If there is a typographical error or other error in the input set the code will indicate so and stop execution at that point.

If the code completes the input, it will wait for the next instruction. For example, the output file name can be connect to the logical unit which is #7 for the line printer output and logical unit #10 for the plotter output. The antenna position can now be defined or modified and the desired window changed. The code can than be told to proceed to produce a shadow map.

When the code has completed the shadow calculation, the user can change the source location, the window of the map, or input another structure and run the code again; or he can print the map out. The map is an array of pixels (doubly dimensioned character array) that are in general either a blank representing a clear path or a character representing a blocked path. The character is normally a uniform character such as an "X". There is an option to tag a particular plate with a character that you define, or the code will letter each plate and cylinder separately. This is useful to determine which plates get in the way or for debugging purposes. More details on this will be given in Chapter 6.

3.4 Non-Interactive Commands

The non-interactive commands needed in this code are a subset and a slight extension of those used in version 2 of the NEC-BSC [1]. The total list of the available non-interactive commands are given in Table 3.1. Only the commands of interest to the obscuration code are defined in this manual. The rest can be found in reference [1] or in later reports and manuals for newer versions of the codes. This section is intended to give the user a brief overview of the specific commands of interest with the details coming in the next Chapter.

The input commands words are intended to make it convenient for the user to define the geometry of the structure without having to define information not needed or repeat information already defined. They are two letter pairs. The rest of the characters on a command word line can be used for comments, since only the first two letters are interpreted.

There is a place in the code to place default data that will be present without a call to the command. This is convenient when a specific resolution sized of the shadow map is desired as a default, for example. The default window can be initial theta angles of 0 to 180 in steps of 2 degrees and initial phi angles of 0 to 360 in steps of 2 degrees by defining the proper variables in this default section. A call to the VF command will over ride this data if it is specified in the input set.

The geometry information is by default assumed to be in meters in a definition coordinate system that is initially the reference coordinate system. The units can be changed using the UN command to either inches or feet or back to meters again. Once the UN command is specified all information after that command is assumed to be in those units unless changed by another call to UN. There is also provision for using any conversion fac-

COMMAND	DEFINITION	LOCATION
BP	back or bistatic scatter	[1]
CC	cone frustum geometry	pg 24
CE	last or only comment	pg 30 or [1]
CG	cylinder geometry	pg 27 or [1]
CM	comment card	pg 30 or [1]
EN	end execution	pg 30 or [1]

UF	model scale factor	pg 42 or [1]
UN	units of geometry	pg 42 or [1]
US	units of source size	[1]
VD	volumetric cut (integer)	not documented
VF	volumetric far zone cut	pg 44
VN	volumetric near zone cut	not documented
VP	volumetric plotter output	not documented
XQ	execute code	pg 47 or [1]

Table 3.1: Table of non-interactive commands.

tor desired. It is input using the UF command and is a scale factor multiplying times all the input dimensions in whatever unit have been defined. The code then takes the input information and changes it internally and stores it in meters, in order to have a uniform system in which to operate. The input dimensions and the internal dimensions are output in the feed back print out sent to a file so the user can see what happened. The dimensions of the source itself, that is length and width not its position, is handled with a default of wavelengths. This can be changed with the US. The length and width of the source is not important in this code so it can be ignored here.

The reference coordinate system is really whatever is convenient for the user. The definition coordinate system is the same as this initial reference system or it can be changed using the rotate translate command RT. The RT command allows allows the user to relocate the origin and orientation of the definition coordinate system with respect to the reference coordinate system. The definition system stay a defined for all subsequent geometry input until it is changed. The RT command's definition is always referenced to the reference coordinate system NOT to itself, that is, one does not put in inverse locations and angles to undo the command, but resets it to the zero position of the origin and the z-axis and x-axis of the reference coordinate system. Note that all angles are assumed to be input in degrees. The coordinate axes are input in a uniform way through out the code by treating the new axes vectors as if they were radial vectors in the system being used. That is the z-axis is defined using a theta and phi angle relative to the reference coordinate system in the RT command and likewise the x-axis is treated as a radial vector. The y-axis is defined by a cross product between the x and z axes. The code checks that the x and z axes were defined orthogonal to one another. If not an error message will result and the code will stop.

The geometry commands are the PG command for the plates, the GP command for the infinite ground plane, the CG command for an elliptic cylinder, and the CC command for the cone frustum cylinders. The plates are defined by inputting the number and location of their corners in the definition system. The ground plane is defined as a infinite plane lying in the x-y plane of the definition coordinate system. The elliptic cylinder definition is base on the location of its origin and the orientation of its z- and x-axes relative to the definition coordinate system. In addition, the radius along its cylinder x-axis and the radius along its cylinder y-axis, along with the z-axis position and angular orientation of its end caps are needed. The cone frustum's definition is similar except that the number of rims making up the cylinder need to be specified and the orientation of the rims does not, since they can't be cut at an angle as in the elliptic cylinder case. For the plates and cylinders the code automatically adds up the number of calls to the commands and counts that as the number of plates or cylinders specified. Only one infinite ground plane can be defined.

The location of the sources are specified by their location, type, orientation, and relative weights using the SG command. Only the location information is important to the obscuration code. Each source specified is automatically counted and remember as the number of sources. Unlike the plates and cylinders, the obscuration code only calculates one source at a time for a shadow map. In non-interactive mode, it does one source at a time producing a map for each. In interactive mode, it takes the first one as the default source and then each subsequent one needs to be interactively input. Receivers are not recognized by the shadow code, so if in reality you are studying a receiver, it must be input as a source not a

receiver for shadowing purposes.

In order to negate already defined commands for the geometry which is automatically increasing their number, a series of commands have been implemented. The plates can be reset to zero using the NP command. The ground plane with NG, the cylinders with NC, the sources with NS, and the entire run can be reset with the NX command.

The code is told to go and execute the interactive mode if it is available, or to go and execute the shadow calculations if the interactive mode has not been implemented using the XQ command. The EN command tells it to exit back to the operating system.

The next section will discuss an overview of the interactive commands and examples of these commands are given in Chapter 7.

3.5 Interactive Commands

The interactive commands provided by the code under VMS are designed to allow easy specification of commonly changed parameters with a syntax which is well-known to users of VMS, the DCL command interpreter syntax. To acquaint the reader with the appearance of these commands, they are summarized below. Detailed descriptions of each command complete with examples can be found in the Chapter 5 on interactive commands. A list of the available interactive commands are given in Table 3.2.

There are interactive commands to allow the user to control the operation of the code or to change or view the geometry. The SHADOW command produces the shadow map. The HELP command gives a descriptions of the commands. The EXIT command exits the user back to the operating system. The SPAWN command allows the use of DCL command while the user is still in the shadow code.

The rest of the commands either allow the user to change the geometry, with the SHOW commands, or see the present status of the geometry, with the SET commands. Most of them have a non-interactive command to which they are at least somewhat associated. The SET UNITS command allows the units of the antenna location to be chosen, similar to the UN command. The SET SCALE_FACTOR command is like the UF command, which allows an arbitrary scale factor for the geometry to be chosen. The SET COORDINATES command allows the definition coordinate system to be change, like in the RT command. The SET ANTENNA command enables the user to interactively specify the antenna location in the definition coordinate system. It is related to the SG command. The SET PATTERN_CUT command allow the user to specify the orientation of the pattern coordinate system in the reference coordinate system. The SET WINDOW command enables the initial, final and incremental angles of the shadow map to be specified. These two commands are related to the VF command.

The next four commands do not have non-interactive commands to which they are related. The SET INPUT command allows the user to specify what file containing the non-interactive commands is to be read. The SET OUTPUT command enables the specification of which output files are to be assigned and their names. The SET FILL_CHARACTER command allows the user to define the symbols that are used for the plate and cylinder shadows. The SET KEYPAD_MODE command enables the VT100 keypad to be used for command definitions as is discussed in the next section, otherwise, the keypad can be used for numerical input. These four commands are discussed much more thoroughly in

3.6 Keypad Use

The definable keypad functions are available for the interactive version of the code only. The keypad definitions are made possible through the use of an integrated VMS screen/terminal management package called SMG. It is a collection of runtime library routines which perform terminal I/O and intercept the special sequences transmitted by the keypad keys. When one of these keys are pressed, the text definition associated with the key is substituted onto the command line. All of this I/O is transparent to the user so that he need only worry about making the initial keypad definitions. For more information about SMG, the reader is referred to the VMS runtime library reference manual.

The keypad definitions are initialized by a text file containing suitable "DEFINE/KEY" commands. The file is called SHADOW.KPD and must reside in the default directory of the user running the code. There is a template file provided with the code which may be customized by the user. The predefined definitions of the VT100 keypad are shown in Table 3.3. Note that the "gold" enables the lower case action in the top row, that is, in most case the "SHOW" operation instead of the "SET" operation.

Chapter 4

Non-Interactive Commands

The non interactive commands discussed in this chapter are a subset of the commands used for the NEC-BSC2. The shadow code will recognize the entire set of NEC-BSC2 commands plus a few new ones. The new commands and some of the old ones that are pertinent to this code will be described here. The following sections define in detail each command word and the variables associated with them. This chapter is organized in alphabetical order of the commands. It is intended to be used as a reference for the user. Chapter 7 will give specific examples using this input method.

The method used to input data into the computer is presently based on a command word system. This is especially convenient when more than one problem is to be analyzed during a computer run. The code stores the previous input data such that one need only input that data which has to be changed from the previous execution. Also, there is a default list of data so for any given problem the amount of data that needs to be input has been shortened. The command word options presently available are listed in Table 3.1 on page 16. The colon after the command word is not necessary and is sometimes used just to illustrate the separation between the command word and the space where comments can be inserted.

In this system, all linear dimensions may be specified in either meters, inches, or feet and all angular dimensions are in degrees. All the dimensions are eventually referred to a fixed cartesian coordinate system used as a common reference for the source and scattering structures. There is, however, a geometry definition coordinate system that may be defined using the RT command. This command enables the user to rotate and translate the coordinate system to be used to input any selected data set into the best coordinate system for that particular geometry. Once the RT command is used all the input following the command will be in that rotated and translated coordinate system until the RT command is called again. See below for more details. There is also a separate coordinate system that can be used to define a pattern coordinate system. This is discussed in more detail in terms of the VF command.

It is felt that the maximum usefulness of the computer code can be achieved using it on an interactive computer system. As a consequence, all input data are defined in free format such that the operator need only put commas between the various inputs. This allows the user on an interactive terminal to avoid the problems associated with typing in the field length associated with a fixed format. This method also is useful on batch processing computers. Note that all read statements are made on unit #5, i.e., READ(5,*), where

the "*" symbol refers to free format. Other machines, however, may have different symbols representing free format.

In all the following discussions associated with logical variables a "T" will imply true, and an "F" will imply false. The complete words true and false need not be input since most compilers just consider the first character in determining the state of the logical variable.

4.1 Command CC: Cone Frustum Geometry

This command enables the user to define the geometry of the finite elliptic conical cylinder structures to be considered. The geometry is illustrated in Figure 4.1. One call to this command defines one cylinder. The number of cylinders in the structure are automatically counted by the number of calls to this command.

READ:	(XCL(N,MC),N=1,3)
	where
	XCL(N,MC) This is a doubly dimensioned real variable. It is used to specify the location of the origin of the MCth elliptic cylinder relative to the definition coordinate system. It is input on a single line with the real numbers being the x,y,z coordinates of the origin which correspond to N=1,2,3, respectively.
READ:	TCLZ, PCLZ, TCLX, PCLX
	where
	TCLZ, PCLZ These are real variables. They are input in degrees as spherical angles that define the z _c -axis of the cylinder coordinate system as if it was a radial vector in the definition coordinate system.
	TCLX,PCLX These are real variables. They are input in degrees as spherical angles that define the x_c -axis of the cylinder coordinate system as if it was a radial vector in the definition coordinate system.
	Note that the new x_c -axis and z_c -axis must be defined orthogonal to each other. The new y_c -axis is found from the cross product of the x_c - and z_c -axes.
READ:	NEC(MC)
	where
	NEC(MC) This is a dimensioned integer variable which defines the number of edges the conical cylinder has.
READ:	AC(NC,MC), BC(NC,MC), ZC(NC,MC)
	where

- AC(NC,MC) This is a double dimensioned real variable which defines the radius of the NCth rim on the x_c -axis of the MCth elliptic cylinder.
- BC(NC,MC) This is a double dimensioned real variable which defines the radius of the NCth rim on the y_c -axis of the MCth elliptic cylinder.
- ZC(NC,MC) This is a double dimensioned real variable which defines the z position of the NCth rim along the z_c -axis of the MCth elliptic cylinder.

Note that the program will keep increasing the number of cylinders in the solution by the number of calls to this command unless the NC or NX commands are called to reinitialize the cylinder geometry. Also, the ellipticity of a conical structure should remain the same for the entire length of that structure. The most positive rim should be defined first until all NC rims are defined in descending order.

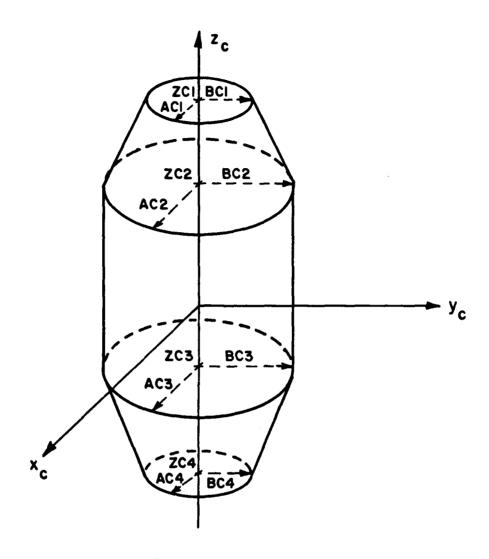

Figure 4.1: Definition of finite cylinder geometry composed of cone frustum segments with elliptic cross section.

4.2 Command CG: Cylinder Geometry

This command enables the user to define the geometry of the finite elliptic cylinder structures to be considered. The geometry is illustrated in Figure 4.2. One call to this command defines one cylinder. The number of cylinders in the structure are automatically counted by the number of calls to this command.

READ:	(ACL(14,1VIC),14=1,5)			
	where			
	XCL(N,MC) This is a doubly dimensioned real variable. It is used to specify the location of the origin of the MCth elliptic cylinder relative to the definition coordinate system. It is input on a single line with the real numbers being the x,y,z coordinates of the origin which correspond to N=1,2,3 respectively.			
READ:	TCLZ, PCLZ, TCLX, PCLX			
	where			
	TCLZ, PCLZ These are real variables. They are input in degrees as spherical angles that define the z _c -axis of the cylinder coordinate system as if it was a radial vector in the definition coordinate system.			
	TCLX,PCLX These are real variables. They are input in degrees as spherical angles that define the x_c -axis of the cylinder coordinate system as if it was a radial vector in the definition coordinate system.			
	Note that the new x_c -axis and z_c -axis must be defined orthogonal to each other. The new y_c -axis is found from the cross product of the x_c - and z_c -axes.			
READ:	AC(1,MC), BC(1,MC)			
	where			
	AC(1,MC) This is a double dimensioned real variable which defines the radius of the MCth elliptic cylinder on the x_c -axis of the cylinder.			
	BC(1,MC) This is a double dimensioned real variable which defines the radius of the MCth elliptic cylinder on the y_c -axis of the cylinder.			

1	
where	

- **ZCN** This is a real variable that defines the position the center of the most negative end cap on the z_c -axis of the cylinder.
- **THTN** This is a real variable. It is input in degrees and defines the angle the surface of the most negative end cap makes with the positive z_c -axis in the x_c - z_c plane.
- ZCP This is a real variable that defines the position of the center of the most positive end cap on the zc-axis of the cylinder.
- **THTP** This is a real variable. It is input in degrees and defines the angle the surface of the most positive end cap makes with the positive z_c -axis in the x_c - z_c plane.

Note that the program will keep increasing the number of cylinders in the solution by the number of calls to this command unless the NC or NX commands are called to reinitialize the cylinder geometry.

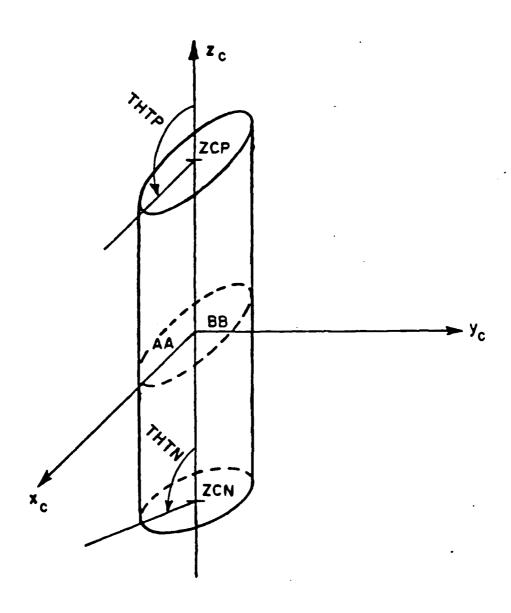

Figure 4.2: Definition of finite elliptic cylinder geometry.

4.3 Command CM: and CE: Comments

These commands enable the user to place comment cards in the input and output data in order to help identify the computer runs for present and future reference.

READ: (IR(I), I=1,36)		
	where	

IR(I) This is a CHARACTER*2 dimensioned array used to store the command word and comments. Each card should have CM or CE on them followed by an alphanumeric string of characters. The CM command implies that there will be another comment card following it. The last comment card must have the CE command on it. If there is only one comment card the CE command must be used.

Note that it is possible to place comments to the right of all the command words, if desired.

4.4 Command EN: End Program

This command enables the user to terminate the execution of the scattering code.

4.5	Commar	hr	GP:	Ground	d P	lane
-----	--------	----	-----	--------	-----	------

i nis command	enables	tne user	to specify	an infinite	ground	plane in	the x_t - y_t	plane.

READ: LSLAB(MPDX)

 where	

LSLAB(MPDX) This is a dimensioned integer variable. It is used to define the type of plate desired as follows:

0 = Perfectly conducting metalic plate

-3 = Dielectric half space

Note that if LSLAB(MPDX)=0 the code will skip around the READ statement for the dielectric information, therefore, the next line defining the dielectric properties should not be placed in the input data set.

READ: ERSLAB(1,MPDX), TESLAB(1,MPDX), URSLAB(1,MPDX), TMSLAB(1,MPDX)

 where		

- ERSLAB(1,MPDX) This is a doubly dimensioned variable. It is used to specify the relative dielectric constant of the half space.
- **TESLAB(1,MPDX)** This is a doubly dimensioned variable. It is used to specify the dielectric loss tangent if the number is positive or the conductivity if the number is negative of the half space.
- URSLAB(1,MPDX) This is a doubly dimensioned variable. It is used to specify the relative permeability constant of the half space.
- TMSLAB(1,MPDX) This is a doubly dimensioned variable. It is used to specify the permeability loss tangent of the half space.

4.6 Command NC: Next Set of Cylinders

This command enables the user to initialize the cylinder data. All of the cylinders are removed from the problem unless they are respecified following this command.

4.7 Command NG: No Ground Plane

This command enables the user to initialize the infinite ground plane. The ground plane is removed from the problem unless it is respecified following this command.

4.8 Command NP: Next Set of Plates

This command enables the user to initialize the plate data. All of the plates are removed from the problem unless they are respecified following this command.

4.9 Command NS: Next Set of Sources

This command enables the user to initialize the source data. All of the sources are removed from the problem unless they are respecified following the command.

4.10 Command NX: Next Problem

This command enables the user to initialize the commands to their default conditions specified in the list at the beginning of the main program.

4.11 Command PG: Plate Geometry

This command enables the user to define the geometry of the flat plate structures to be considered. The geometry is illustrated in Figure 4.3. One call to this command defines one plate. The number of plates in the structure are automatically counted by the number of calls to this command.

READ:	MEP(MP), LSLAB(MP)				
	where				
	MEP(MP) This is a dimensioned integer variable. It is used to define the number of corners (or edges) on the MPth plate.				
	LSLAB(MP) This is a dimensioned integer variable. It is used to define the type of plate desired as follows:				
	1 = Transparent thin dielectric slab				
	0 = Perfectly conducting metalic plate				
	-2 = Dielectric covered plate				
	Note that if LSLAB(MP)=0 the code will skip to the read statements associated with the corners XX(N,ME,MP). Therefore, the information for the different slab layers should not be put in the data list for the perfectly conducting plate.				
READ:	NSLAB(MP)				
	where				
	NSLAB(MP) This is a dimensioned integer variable. It is used to define the number of dielectric layers on the MPth plate.				
READ:	DSLAB(NS,MP), ERSLAB(NS,MP), TESLAB(NS,MP), URSLAB(NS,MP), TMSLAB(NS,MP)				
	where				
	DSLAB(NS,MP) This is a doubly dimensioned variable. It is used to specify the thickness of the NSth layer.				
	ERSLAB(NS,MP) This is a doubly dimensioned variable. It is used to specify the relative dielectric constant of the NSth layer.				

the number is negative of the NSth layer.

TESLAB(NS,MP) This is a doubly dimensioned variable. It is used to specify the dielectric loss tangent if the number is positive or the conductivity if

URSLAB(NS,MP) This is a doubly dimensioned variable. It is used to specify the relative permeability constant of the NSth layer.

TMSLAB(NS,MP) This is a doubly dimensioned variable. It is used to specify the permeability loss tangent of the NSth layer.

Note there w	un de Maryrik	(P) number of lines of	oi the above data.	

 where	
 where	

XX(N,ME,MP) This is a triply dimensioned real variable. It is used to specify the location of the MEth corner of the MPth plate. It is input on a single line with the real numbers being the x,y,z coordinates of the corner, in the specified coordinate system, which corresponds to N=1,2,3, respectively, in the array. For example, the array will contain the following for plate #1 and corner #2 located at x=2., y=4., z=6.:

XX(1,2,1)=2.XX(2,2,1)=4.

XX(3,2,1)=6.

This data is input as: 2.,4.,6.

This read statement will be called MEP(MP) times so that all the corners are defined. As an example, the input data for the flat plate structure given in Figure 4.3, is given by

4,0 :corners and type of plate
1., 1., 0. :corner #1
-1., 1., 0. :corner #2
-1.,-1., 0. :corner #3
1.,-1., 0. :corner #4.

See elsewhere for further details on how to number the corners. Note that the program will keep increasing the number of plates in the solution by the number of calls to this command unless the NP or NX commands are called to reinitialize the plate geometry.

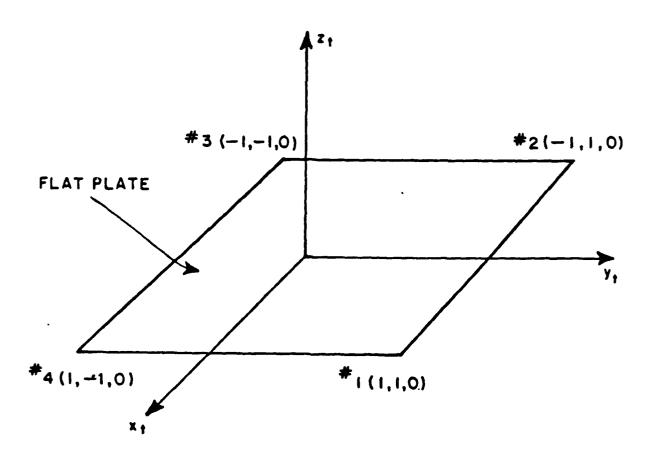

Figure 4.3: Definition of flat plate geometry.

4.12 Command RT: Rotate-Translate Geometry

This command enables the user to translate and/or rotate the coordinate system used to define the input data in order to simplify the specification of the plate, cylinder, and source geometries. The geometry is illustrated in Figure 4.4.

- THZP,PHZP These are real variables. They are input in degrees as spherical angles that define the z-axis of the new coordinate system as if it was a radial vector in the reference coordinate system.
- THXP,PHXP These are real variables. They are input in degrees as spherical angles that define the x-axis of the new coordinate system as if it was a radial vector in the reference coordinate system.

The new x-axis and z-axis must be defined orthogonal to each other. The new y-axis is found from the cross product of the x- and z-axis. All the subsequent inputs will be made relative to this new coordinate system, which is shown as x_t, y_t, z_t , unless command RT is called again and redefined.

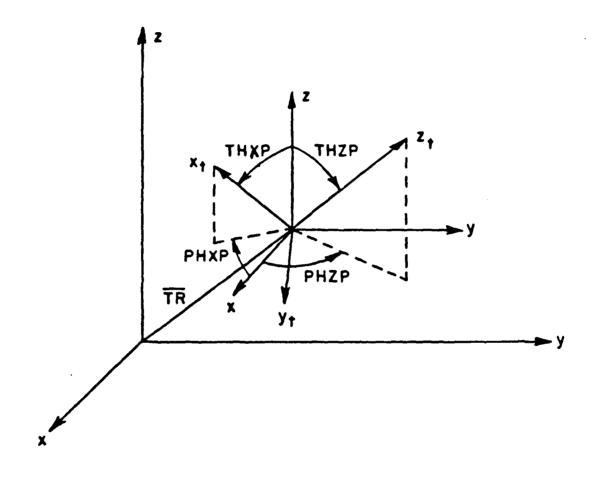

Figure 4.4: Definition of rotate-translate coordinate system geometry.

4.13 Command SG: Source Geometry

This command enables the user to specify the location and type of source to used. The geometry is illustrated in Figure 4.5 and 4.6. One call to this command defines one source. The number of sources in the problem are automatically counted by the number of calls to this command and the SA command.

READ:	(XSS(N,MS),N=1,3)				
	where				
	XSS(N,MS) This is a doubly dimensioned real array which is used to define the x,y,z location of the MSth element in the definition coordinate system. Again, a single line of data contains the x,y,z (N=1,2,3) locations.				
READ:	THSZ, PHSZ, THSX, PHSX				
	where				
	THSZ,PHSZ These are real variables which are used to define the orientation of the MSth element in the definition coordinate system. They are input in degrees as spherical angles that define a radial direction which is parallel to the MSth current flow for a dipole antenna or which is parallel to the length of an aperture antenna.				
	THSX,PHSX These are real variables which are used to define the orientation of the MSth element in the definition coordinate system. They are input in degrees as spherical angles that define a radial direction which is parallel to the MSth elements aperture width or which is parallel to a slot's width. For a dipole antenna, these angles can be made in a convenient direction.				
	The x-axis and z-axis specified by these angles must be defined orthogonal to each other. The y-axis is found by the cross product of the x- and z-axes.				
READ:	IMS(MS), HS(MS), HAWS(MS)				
	where				
	IMS(MS) This is an integer array which is used to define the MSth element's				

The designations are defined as follows:

IMS(MS)<0 for an electric element

IMS(MS)>0 for a magnetic element

|IMS(MS)|=1 for a uniform current distribution

|IMS(MS)|=2 for a piece-wise sinusoidal distribution

|IMS(MS)|=3 for a TE01 cosine current distribution

- HS(MS) This is a real array which is used to input the length of the MSth element.
- HAWS(MS) This is a real array which is used to input the width of the MSth element in the case of an aperture antenna. If HAWS(MS)=0, then it is assumed to be a dipole.

Note that the units of the variable HS(MS) and HAWS(MS) can be specified by the US command. If wavelength is chosen as the units then all the sources must be specified in wavelengths.

READ:	WMS,	WPS		
			where	

WMS, WPS These are real variables used to define the excitation associated with the MSth element. The magnitude is given by WMS and the phase in degrees by WPS.

Note that the program will keep increasing the number of sources in the solution by the number of calls to this command unless the NS or NX commands are called to reinitialize the source geometry.

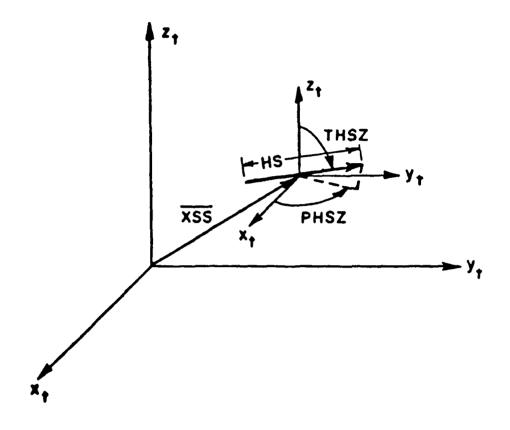

Figure 4.5: Definition of source geometry for dipole antennas.

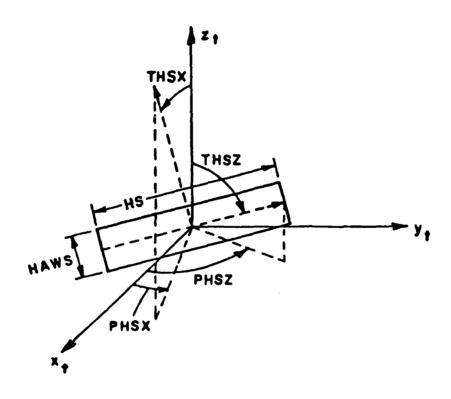

Figure 4.6: Definition of source geometry for aperture antennas.

4.14	Command UF: Scale Factor
	mand enables the user to scale the linear dimensions that follow the command by specified.
READ:	UNITF
	where
	UNITF This is a real variable that is used as a scale factor for all the linear dimensions that follow the command.
4.15	Command UN: Units of Geometry
after the	mand enables the user to specify the units of all the linear dimensions to be input command is called. (The exceptions are the source length HS and width HAWS, wer length HR and width HAWR, see command US.)
READ:	IUNIT
	where
	IUNIT This is an integer variable that indicates the units for the input data that follows, such that
	1= meters
	2= feet 3= inches
4.16	Command US: Units of Source
HAWS or	mand enables the user to specify the units of the source length HS and width receiver length HR and width HAWR to be input after the command is called. iables are in the commands SG, SA, RG, and RA.

IUNST This is an integer variable that indicates the units for the input data HS, HAWS, HR, HAWR that follows, such that if

_ where _

READ: IUNST

0= wavelengths

1= meters

2= feet

3= inches

Note that if the units are specified to be wavelengths for one source it must be wavelengths for all the sources specified.

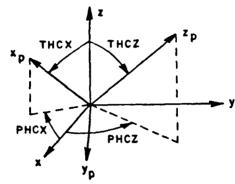

4.17 Command VF: Far Zone Volumetric Pattern

This command enables the user to define the far zone volumetric pattern coordinate system, the pattern cut, and the angular range that is desired. The geometry is illustrated in Figure 4.7.

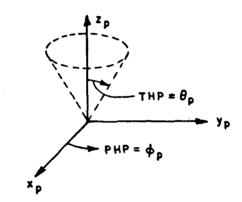

AD:	THCZ, PHCZ, THCX, PHCX
	where
	THCZ,PHCZ These are real variables. They are input in degrees as spherical angles that define the z_p -axis of the pattern coordinate system as if it was a radial vector in the reference coordinate system.
	THCX,PHCX These are real variables. They are input in degrees as spherical angles that define the x_p -axis of the pattern coordinate system as if it was a radial vector in the reference coordinate system.
	Note that the new x_p -axis and z_p -axis must be defined orthogonal to each other. The new y_p -axis is found from the cross product of the x_p - and z_p -axes.
AD:	LCNPAT, TPPD, TPPV, NPV
	where
	LCNPAT This is a logical variable that defines the pattern cut desired, such that
	T= The theta angle is held fixed while the phi angle is varied. The theta angle will then be incremented and another cut will be calculated.
	F= The phi angle is held fixed while the theta angle is varied. The phi angle will then be incremented and another cut will be calculated.
	TPPD This is a real variable. It defines the starting angle of the "fixed" angle specified by LCNPAT.
	TPPV This is a real variable. It defines the incremental angle of the "fixed" angle specified by LCNPAT.
	NPV This is a integer variable. It defines the number of pattern points of the "fixed" angle specified by LCNPAT.
AD:	TPPS, TPPI, NPN
	where

TPPS This is a real variable. It defines the starting angle of the "varying" angle specified by LCNPAT.

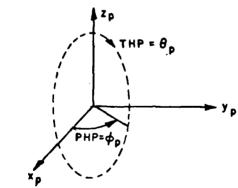

- TPPI This is a real variable. It defines the incremental angle of the "varying" angle specified by LCNPAT.
- NPN This is a integer variable. It defines the anumber of pattern points of the "varying" angle specified by LCNPAT.

a. Definition of pattern coordinate system.

b. Conic pattern cut, LCNPAT=.TRUE., TPPD=THP.

c. Constant Phi pattern cut, LCNPAT=.FALSE., TPPD=PHP.

Figure 4.7: Definition of volumetric pattern coordinate system.

4.18 Command XQ: Execute Code

This command is used to execute the code so that the results may be computed. After execution the code returns for another possible command word.

Chapter 5

Interactive Commands

5.1 Overview

Facilities for interactive programs vary greatly from one operating system to the next with little or no standardization between systems. In spite of this, it was felt that the users of this code would benefit immensely from an interactive mode of operation. In order for the code to have interactive capability without an excessive amount of development time, the developers have used many features of the DEC VAX/VMS operating system. Since many engineers presently have access to the DEC VAX, it is felt that this will lead to reasonable transportability of the interactive mode for this code.

This decision has several ramifications for users of the SHADOW code. It means that the commands described in this chapter do not exist on computers that don't run VAX/VMS Version 4.0 or greater. It also means that this code has been separated into two parts, one standard FORTRAN 77 and the other VMS dependent containing the interactive facility, with a slightly different main program for the non-interactive code.

5.2 Command Descriptions

This section describes the interactive SHADOW commands in detail complete with examples for each. The syntax of the interactive commands is that of the Digital Command Language or DCL and for obvious reasons familiarity with the syntax of DCL is assumed throughout this chapter. For details about the utilities used to perform this DCL style command parsing, readers are referred to the VMS documentation concerning the Command Definition Utility or CDU.

EXIT	Causes the program to exit	i.			
FORMAT	EXIT				
	Command Qualifiers None.	Defaults None.			
restrictions	None.				
prompts	None.				
command parameters	None.				
DESCRIPTION	All output files are closed,	and control is returned to DCL.			
COMMAND QUALIFIERS	None.				
EXAMPLES					
\$ RUN SHADOW SHADOW> SHADOW> EXIT \$					

This example shows how to exit the program.

HELP	Displays information about SHADOW commands or help tany other library you specify.				
FORMAT	HELP help-item				
	Command Qualifiers /LIBRARY[=library-name]	Defaults /LIB=SYS\$DISK:[]SHADOW			
restrictions	The indicated help files must exist.				
prompts	None.				
command parameters help-item The help-item is a keyword which is the item you want h					
DESCRIPTION	The SHADOW help command adheres to the conventions of VMS help libraries in form and content.				

EXAMPLES

COMMAND

QUALIFIERS

SHADOW> HELP SET OUTPUT

(SET OUTPUT help message)

/LIBRARY[=library-name]

/NOLIBRARY

Topic? EXIT

. (EXIT help message)

Topic? <RETURN>

SHADOW> HELP/LIBR=HELPLIB LOGOUT

. (LOGOUT help message from the system help library)

Controls whether an alternate help library will be used in the search for topics. This qualifier must appear immediately after the HELP command or it will be interpreted as part of the help-item. If you

specify /NOLIBRARY then no library will be searched.

Topic? <RETURN> SHADOW>

The above examples show how to get help about shadow topics and how to access other VMS help libraries with the HELP command

C	u	A	n	N'	۱A	v
J	H,	M	יע	U	V١	٧.

Initiates the obscuration calculation for the current antenna location and input geometry.

FORMAT	SHADOW				
	Command Qualifiers None.	Defaults None.			
restrictions	None. Command may be abbreviated "S".				
prompts	None.				
command parameters					
DESCRIPTION	The commands which alter parameters, such as SET WINDOW and SET ANTENNA do not initiate shadowing calculations automatically. This is to avoid redundant calculations when several parameters are changed at once. Once desired parameters are set, the SHADOW command performs the obscuration calculations and out puts the result.				
COMMAND	None.				

QUALIFIERS EXAMPLES

SHADOW> SET ANTENNA

Input antenna location in meters: 11,22,32

Antenna in RCS (meters): 11.00000 22.00000 32.00000 Definit system (meters): 11.00000 22.00000 32.00000

SHADOW> SHAD Working...

SHADOW> SET ANTENNA

Input antenna location in meters: 10,20,30

Antenna in RCS (meters): 10.00000 20.00000 30.00000 Definit system (meters): 10.00000 20.00000 30.00000

SHADOW> S Working... SHADOW> The above commands all calculate the projected shadows for two different antenna locations on given input geometry. The results all go into the same output file, because no "SET OUTPUT" command was executed in between "SHADOW" commands.

•	P	A	١.	R /	A	ŧ
•	м.	ш	u	v	и	1
•			٧.			

Creates a subprocess for executing DCL commands without exiting the SHADOW program. This command is useful for executing DCL commands without reinitializing the context of a SHADOW program session.

FORMAT

SPAWN command-string

Command Qualifiers None.

Defaults None.

restrictions

A few restrictions are imposed by VMS.

oThe RESOURCE_WAIT state must be enabled for the spawning process.

oRequires TMPMBX or PRMMBX user privileges.

oSPAWN does not manage terminal characteristics.

Command may be abreviated "\$", where the blank after the \$ is necessary.

prompts

None.

command parameters

command-string

Specifies a DCL command string to be executed in the context of the subprocess. SHADOW will wait until the subprocess completes executing. If command-string is blank, the subprocess will prompt for commands repeatedly.

DESCRIPTION

The details of the spawn command are exactly as documented in the DCL dictionary, volume 2 of the VAX/VMS documentation set.

COMMAND QUALIFIERS

None.

EXAMPLES

SHADOW> SPAWN SHOW USERS

VAX/VMS Interactive Users 11-DEC-1985 08:34:18.72

SHADOW>

The above spawn command illustrate how DCL commands may be executed without exiting the SHADOW program.

SET ANTENNA LOCATION

Determines the location of the source point, or the center of the far-zone sphere for subsequent shadowing calculations.

FORMAT	SET ANTENNA				
	Command Qualifiers Defaults None. None.				
restrictions	Its recommended that the antenna not be placed in the interior of a cylinder. Unusual results may occur if this is done.				
prompts	Input antenna location in meters: Input antenna location in feet: Input antenna location in inches:				
command parameters	None.				
DESCRIPTION	in the current units and defini UNITS and the SET COOR command does NOT accept	s of the (x,y,z) components of a vector tion coordinate system, set by the SET DINATE commands, respectively. The the antenna location on the command ad. The input syntax for the numbers of RTRAN read.			
COMMAND QUALIFIERS	None.				

EXAMPLES

SHADOW> SET ANTENNA

Input antenna location in meters: 10,20,30

Antenna in RCS (meters): 10.00000 20.00000 30.00000 Definit system (meters): 10.00000 20.00000 30.00000

This example sets the antenna location to 10.,20.,30. (x,y,z) in the current units, which are meters.

EXAMPLES

SHADOW> SET UNIT FEET

SHADOW> SET ANT

Input antenna location in feet : 10,20,30

Antenna in RCS (meters): 3.04800 6.09600 9.14400 Definit system (feet): 10.00000 20.00000 30.00000

SHADOW>

This example shows how the antenna location is interpreted in the units of feet.

SET COORDINATES

Sets up a coordinate transformation to be applied to subsequent geometry.

FORMAT	SET COORDINATES				
	Command Qualifiers Defaults None. None.				
restrictions	The specified coordinate axes must be orthogonal to one another. Please input a translation vector in feet: Please input THZP,PHZP,THXP,PHXP in degrees:				
prompts					
command parameters	None.				
DESCRIPTION	The antenna location may be specified relative to an alternative co ordinate system. This coordinate system is established via the SET COORDINATES command. It does not affect the pattern cut coordinate system.				
COMMAND QUALIFIERS	None.				

EXAMPLES

SHADOW> SET COOR

Please input a translation vector in feet : 100,200,300 Please input THZP,PHZP,THXP,PHXP in degrees: 0, -54, 265.5, 45

- * The following rotations are used for ALL subsequent inputs:
- * VRS(1,1) = -0.70711 VRS(1,2) = -0.70711 VRS(1,3) = 0.00000
- * VRS(2,1)= 0.70711 VRS(2,2)= -0.70711 VRS(2,3)= 0.00000 *
- * VRS(3,1)= 0.00000 VRS(3,2)= 0.00000 VRS(3,3)= 1.00000

The above example shows how a default coordinate system may be established. The program echoes the established coordinate axes. These may be re-examined at any time with the SHOW COORDINATE command.

SET FILL_CHARACTER

Allows selection of the characters used to fill the output. Can be used to highlight particular elements of a geometry.

	_		
FΩ	n		
-11	ĸ	11.71	/A I

SET FILL [tag-character]

Command Qualifiers	Defaults	
/SEQUENTIAL	None.	
/PLATE=(num[,char])	None.	
/CYLINDER=(num[,char])	None.	

restrictions

None.

prompts

None.

command parameters

tag-character

Is any single ASCII character. If a lowercase letter is desired, enclose the letter in double quotes, i.e. "a". The default is "X".

DESCRIPTION

In order to better trace portions of a geometry through the shadowing process, the ability to tag a particular cylinder or plate has been added. The tag setting remains in effect until altered by a subsequent "SET FILL" command. The highlighted plate or cylinder appears in its entirety in the output regardless of its actual position in the hierarchy of obscuration. This allows the user to be absolutely certain of the shadowing caused by the particular highlighted geometry.

There are three tagging modes available. One is sequential tagging. In this mode, the code attempts to assign a unique character in the output to each plate/cylinder in the input. Plates are numbered beginning with "A" and increasing through the ASCII character sequence, and cylinders are treated the same way beginning with "1".

The second mode causes all parts of the geometry to be shaded with a single specified character such as "X". In this total obscuration mode, any one part of the input geometry is not easily identified—rather the total obscuration is presented homogeneously. It is specified using SET FILL without qualifiers. The third mode is the same as the second mode, but with the added feature of one single plate (or cylinder) highlighted with a different character. In this mode the relation of one part of the geometry to the rest is clearly

visible. This mode can be very helpful when isolating particular parts of a geometry that are shadowing the source.

COMMAND QUALIFIERS

/SEQUENTIAL /SEQUENTIAL

The /SEQUENTIAL qualifier selects the first mode of obscuration, sequential tagging of the input geometry. This qualifier may not be specified with a tag-character parameter nor with any of the other qualifiers.

/PLATE=num

/PLATE=(num,char)

The /PLATE qualifier selects the third mode of obscuration, homogenous tagging with highlighting of a particular plate.

The num argument is the number of the plate to be tagged. It is a required argument. The char argument is the ASCII character to be used when tagging the plate. It is optional, and defaults to "P" if unspecified.

This qualifier may not be specified in combination with other qualifiers. It is mutually exclusive with the /CYLINDER qualifier.

/CYLINDER=num

/CYLINDER=(num.char)

The /CYLINDER qualifier selects the third mode of obscuration, homogenous tagging with highlighting of a particular cylinder. It works exactly like the /PLATE qualifier.

The num argument is the number of the cylinder to be tagged. It is a required argument. The char argument is the ASCII character to be used when tagging the cylinder. It is optional, and defaults to "C" if unspecified.

This qualifier may not be specified in combination with other qualifiers. It is mutually exclusive with the /PLATE qualifier.

EXAMPLES

SHADOW> set fill

No individual plates/cylinders are tagged All geometry marked by [X]

SHADOW> set fill \$

No individual plates/cylinders are tagged All geometry marked by [\$]

SHADOW> set fill * /plate=6 Plate 6 is tagged with [P] All other geometry tagged with [*]

SHADOW> set fill * /plate=(7,%)
Plate 7 is tagged with [%]
All other geometry tagged with [*]

SHADOW> set fill Q /cyl=(2,\$)
Cylinder 2 tagged with [\$]
All other geometry tagged with [Q]

SHADOW> set fill /plate=9 /cyl=4 %CLI-W-CONFLICT, illegal combination of command elements

SHADOW> set fill Q /cyl=(2,\$) /seq %CLI-W-MAXPARM, too many parameters - reenter command with fewer parameters

SHADOW> set fill /seq ! Q /cyl=(2,\$) /seq All cylinders/plates sequentially tagged

The above examples are obvious except possibly the last three. They show that the qualifiers are not allowed in combination, that the /SE-QUENTIAL qualifier does not allow specification of a fill character, and that the DCL syntax ignores everything after an exclamation point.

SET INPUT_SET

Reads an input set from a named file

FORMAT	SET INPUT_SET filename		
	Command Qualifiers None.	Defaults None.	
restrictions	The named input file must exist.		
prompts	input set:		
command parameters	filename		
DESCRIPTION	The set output command has the dual role of designating an input file and simultaneously causing that input set to be read and prepared for subsequent shadow commands. The current output files are NOT affected by this command so that several outputs may be concatenated. Normally though, this command would be entered after a SET OUTPUT command.		
COMMAND QUALIFIERS	None.		

EXAMPLES

SHADOW> SET OUT AN5S1

Plotting file is: USER1: [RJM.NAS] AN5S1.PLT;1

Printer file is: _NLAO:[]FOROO7.DAT;

Input echo file: USER1: [RJM.NAS] AN5S1.LIS;1

SHADOW> SET INPUT AN5S1
The current input set is
USER1: [RJM.NAS] AN5S1.INP;1

The SET OUTPUT command is used to set the output files - the printer output is discarded by default. The input set AN5S1.INP is then read and processed by the SET INPUT command.

SET KEYPAD_MODE

Causes the keypad state to change to non-numeric.

FORMAT	SET [NO]KEYPAD			
	Command Qualifiers None.	Defaults None.		
restrictions	None.			
prompts	prompts None.			
command parameters	None.			
DESCRIPTION	The keypad of most DEC terminals can be in one of two standards meric mode or keypad mode. In numeric mode, the keypad represent the numbers and symbols printed on the keys. In mode, the keys may be defined to provide functions, in n same way as they do in DCL.			
	SET KEYPAD enables the defined-key feature of SHADOW, and SET NOKEYPAD returns the keypad to numeric-entry mode.			
	The keypad definitions are me SHADOW.KPD; in the curre	nade in a session startup file called ent default directory.		
COMMAND QUALIFIERS	None.			

EXAMPLES

SHADOW> SET KEYPAD

The keyboard is in keypad mode.

SHADOW> SET NOKEYPAD

The keyboard is not in keypad mode.

CET	\mathbf{O}	ITP	TIL
3P I		,,,	' () 1

Determines the names of new output files and closes current output files.

FORMAT

SET OUTPUT filename

Command Qualifiers	Defaults
/PLOTTABLE	/PLOTTABLE
/PRINTABLE	/NOPRINTABLE
/ECHOING	/ECHOING

restrictions

The filename must be a valid VMS filename.

prompts

_filename:

command parameters

filename

The name(s) of the newly created output file(s).

DESCRIPTION

There are three different outputs from the shadow program. One is an echo of the input set from the input processor. Another is a line printer output of the shadow map. The third is an output suitable for input to a separate plotting program. The set output command opens these files for the code. The name of the file opened is specified as the filename parameter. The filetypes are set by the command automatically, so that only the filename need be specified.

COMMAND QUALIFIERS

/PLOTTABLE

/NOPLUTTABLE

Causes a plottable output file to be produced. This is the default. Specifying /NOPLOT will override this default.

/PRINTABLE /NOPRINTABLE

Causes an output file to be produced which is suitable for printing on a standard line printer. /NOPRINT is the default. Specifying /PRINT will override this default.

/ECHOING /NOECHOING

Causes the input echo to be saved in a file when a new input set is

read. /ECHOING is the default. Specifying /NOECHO will override this default.

EXAMPLES

SHADOW> SET OUT AN5S1

Plotting file is: USER1: [RJM.NAS] ANDS1.PLT;1

Printer file is: _NLAO:[]FOROO7.DAT;

Input echo file: USER1: [RJM.NAS] AN5S1.LIS;1

SHADOW> SET OUT AN5S1 /PRINT

Plotting file is: USER1: [RJM.NAS] AN5S1.PLT;2
Printer file is: USER1: [RJM.NAS] AN5S1.PRT;1
Input echo file: USER1: [RJM.NAS] AN5S1.LIS;2
SHADOW> SET OUT AN5S1 /NOPLOT /NOECHO /PRINT

Plotting file is: _NLAO:[]FORO10.DAT;

Printer file is: USER1: [RJM.NAS] AN5S1.PRT; 2

Input echo file: _NLAO:[]FOROO6.DAT;

SHADOW> SET OUT AN5S1

Plotting file is: USER1: [RJM.NAS] AN5S1.PLT;3

Printer file is: _NLAO:[]FOROO7.DAT;

Input echo file: USER1: [RJM.NAS] AN5S1.LIS; 3

The above examples show the operation of the SET OUTPUT command. Note that the printer file is not produced by default, and the device NLAO: (the null device) is where the output is discarded.

SET PATTERN_CUT

Specifies the pattern cut coordinate system.

FORMAT	SET PATTERN_CUT			
	Command Qualifiers Defaults None. None.			
restrictions	The specified coordinate axes must be orthogonal. Please input THZP,PHZP,THXP,PHXP in degrees: None.			
prompts				
command parameters				
DESCRIPTION	The shadow map window is specified relative to the pattern-cut co- ordinate system. This system can be changed to facilitate easier specification of this window relative to the blocking object coordi- nate system.			
COMMAND QUALIFIERS	None.			

EXAMPLES

SHADOW> SET PAT

Please input THZP, PHZP, THXP, PHXP in degrees: 0, -54, 265.5, 45, 0, 135

- * The following rotations are used for ALL subsequent inputs:
- * VPC(1,1)= -0.70711 VPC(1,2)= -0.70711 VPC(1,3)= 0.00000
- * $VPC(2,1)= 0.70711 \ VPC(2,2)= -0.70711 \ VPC(2,3)= 0.00000$ *
- * VPC(3,1)= 0.00000 VPC(3,2)= 0.00000 VPC(3,3)= 1.00000

The pattern-cut coordinate system shown has been set up.

SET SCALE_FACTOR

Sets a new value for the uniform scale factor.

FORMAT	SET SCALE_FACTOR			
	Command Qualifiers None.	Defaults None.		
restrictions	The scale factor may not be specified on the command line.			
prompts	Please input a uniform scale factor:			
command parameters	None.			
DESCRIPTION		tibility in specifying input, an additional to numerical inputs. The default value		
COMMAND QUALIFIERS	None.			

EXAMPLES

SHADOW> SET SCALE

Please input a uniform scale factor: 5.5 The uniform scale factor is 5.50000000

The uniform scale factor has been changed to 5.5.

SET UNITS	Sets the default units for the units are Meters, Feet, Inches	he entry of numeric values. Allowable		
FORMAT	SET UNITS keyword			
	Command Qualifiers None.	Defaults None.		
restrictions	None.			
prompts	inches, feet, or meters:			
command parameters	Keyword may be one of the o METERS o FEET o INCHES	following:		
DESCRIPTION		is set, these are the units applied to the alculations are always done in meters.		
COMMAND QUALIFIERS	None.			
EXAMPLES				

This example sets the default units to feet.

SHADOW> SET UNI FEET

SET	18	/ 1 R	חוו		A.
3E I	v	/ II II	VU	U	vv

Sets parameters for windowing of the output.

FORMAT	SET WINDOW			
	Command Qualifiers None.	Defaults None.		
restrictions	maximum span of phi must be resolution is a function of the	a must be less than 180 degrees. The pe less than 360 degrees. The maximum e specified range for both theta and phispecified on the command line.		
prompts	Please enter a new range for theta (lower, higher): Please enter a new THETA resolution in degrees/pixel: Please enter a new range for phi (lower, higher): Please enter a new PHI resolution in degrees/pixel:			
command parameters	None.			
DESCRIPTION	dowing feature was included be mapped onto a larger out does this by prompting for t phi, and the desired levels of	on the presentation of the output, a win- so that portions of theta-phi space may put surface. The set window command he desired range of displayed theta and resolution. The default window displays d phi at a resolution of 2 degrees/pixel		
COMMAND QUALIFIERS	None.			

EXAMPLES

SHADOW> SET WINDOW

The current range of theta in degrees is 0.0000000E+00 to 180.0000 with a resolution of 2.000000 degrees/pixel.

The current range of phi in degrees is 0.0000000E+00 to 360.0000 with a resolution of 2.000000 degrees/pixel.

Please enter a new range for theta (lower, higher): 30,40

Please enter a new THETA resolution in degrees/pixel: .5

Please enter a new range for phi (lower, higher): 45,90

Please enter a new PHI resolution in degrees/pixel: .5

The current range of theta in degrees is 30.00000 to 40.00000 with a resolution of 0.5000000 degrees/pixel.

The current range of phi in degrees is 45.00000 to 90.00000 with a resolution of 0.5000000 degrees/pixel.

The set window command above first displays the current window settings (which also happen to be the default settings), then prompts for new values. The new values are then also shown.

SHOW ANTENNA_LOCATION

Display the current antenna position.

FORMAT	SHOW ANT	SHOW ANTENNA LOCATION			
	Command None.	d Qualifiers		Defaults None.	, seed
restrictions	None.	None.			
prompts	None.				
command parameters	None.	None.			
DESCRIPTION		nna location is Reference Coord	• •	oth the curren	t default units
COMMAND QUALIFIERS	None.				
EXAMPLES					
SHADOW> SHO ANT					
Antenna in RCS (meters):	2.00000	3.00000	4.00000	
Definit system (meters):	2.00000	3.00000	4.00000	

This command displays the current antenna location in both the reference coordinate systems (RCS) and the current default units, which are also meters in this example.

SHOW COORDINATES

Displays the default transformation applied to antenna placement commands.

FORMAT	SHOW COORDINATES			
	Command Qualifiers None.	Defaults None.		
restrictions	None.			
prompts	None.	None.		
command parameters	None.			
DESCRIPTION	The antenna location is input in terms of an antenna coordinate system. This command displays the orientation of this system.			
COMMAND QUALIFIERS	None.			

EXAMPLES

SHADOW> SHO COORD

- * VRS(1,1)= 1.00000 VRS(1,2)= 0.00000 VRS(1,3)= 0.00000
- * VRS(2,1)= 0.00000 VRS(2,2)= 1.00000 VRS(2,3)= 0.00000 *
- * VRS(3,1)= 0.00000 VRS(3,2)= 0.00000 VRS(3,3)= 1.00000 *

In this example, the antenna coordinate system is coincident with the reference coordinate system.

SHOW FILL_CHARACTER

Displays the current output fill modes.

FORMAT	SHOW FILL			
	Command Qualifiers None.	Defaults None.		
restrictions	None.			
prompts	None.			
command parameters	None.			
DESCRIPTION	The output may be generated in one of three modes. For a detailed description of the possible modes, see the SET FILL command.			
COMMAND QUALIFIERS	None.			

EXAMPLES

SHADOW> SHOW FILL
Plate 6 is tagged with [P]
All other geometry tagged with [*]

In the above example, the sixth plate of the input set is tagged with the ASCII character "P". The SET FILL command has many more examples.

SHOW INPUT_SET

Displays the name of the file from which the current geometry was defined.

FORMAT SHOW INPUT_SET Defaults Command Qualifiers None. None. restrictions None. prompts None. command None. parameters **DESCRIPTION** The input set is determined with the SET INPUT command. The SHOW INPUT command echoes this input set filename. COMMAND None. **QUALIFIERS**

EXAMPLES

SHADOW> SHOW INPUT

The current input set is USER1: [RJM.NAS] AN551.INP;1

SHOW KEYPAD_MODE

Displays the current state of the keyboard.

FORMAT	SHOW KEYPAD_MODE			
	Command Qualifiers None.	Defaults None.		
restrictions	orompts None.			
prompts				
command parameters				
DESCRIPTION	The keypad of most DEC terminals can be in one of two states, nu meric mode or keypad mode. In numeric mode, the keypad button represent the numbers and symbols printed on the keys. In keypad mode, the keys may be defined to provide functions, in much the same way as they do in DCL. The keypad definitions are established by a startup file called SHADOW.KPD in the current default directory.			
COMMAND QUALIFIERS	None.			

EXAMPLES

SHADOW> SHOW KEYPAD

The keyboard is not in keypad mode.

The keypad was not in keypad mode in this example.

SHOW OUTPUT

Displays the names of the current output files.

FORMAT	SHOW OUTPUT					
	Command Qualifiers None.	Defaults None.				
restrictions prompts command parameters	None.					
	None.					
	None.					
DESCRIPTION There are three possible output files produced by the shad gram. One is for plotting with a separate plotting program a filetype of .PLT. The second is a line-printer formatted out a filetype of .PRT. The third is the input set listing echo, who be redirected into a file. Its filetype is .LIS.						
COMMAND QUALIFIERS	None.					

EXAMPLES

SHADOW> SET OUTPUT EXAMPLES /PRINT

SHADOW> SHOW OUTPUT

Plotting file is: USER1: [RJM.NAS] EXAMPLE3.PLT; 1
Printer file is: USER1: [RJM.NAS] EXAMPLE3.PRT; 1
Input echo file: USER1: [RJM.NAS] EXAMPLE3.LIS; 1

This example shows how a SET OUTPUT command creates the names shown for output files. See the SET OUTPUT command description for more details.

SHOW PATTERN_CUT

Displays the pattern-cut coordinate system transformation matrix.

FORMAT	SHOW PATTERN_CUT					
restrictions prompts command parameters	Command Qualifiers None.	Defaults None.				
	None.					
	None.					
	None.					
DESCRIPTION The shadow map window is specified relative to the patter ordinate system. This system can be changed to facili specification of this window relative to the blocking objudinate system, that is, the reference coordinat system. information, see the SET PATTERN command on page 6						
COMMAND QUALIFIERS	None.	·				

EXAMPLES

SHADOW> SHOW PATT

- The following rotations are used for ALL subsequent inputs:
- VPC(1,1)= -0.70711 VPC(1,2)= -0.70711 VPC(1,3)= 0.00000
- * VPC(2,1)= 0.70711 VPC(2,2)= -0.70711 VPC(2,3)= 0.00000
- * VPC(3,1)= 0.00000 VPC(3,2)= 0.00000 VPC(3,3)= 1.00000

The pattern-cut coordinate system shown has been set up.

SHOW SCALE_FACTOR

Displays the uniform scale factor currently in effect.

FORMAT	SHOW SCALE_FACTOR					
	Command Qualifiers None.	Defaults None.				
restrictions	None.					
prompts command parameters						
	None.					
DESCRIPTION	command can set a uniform scale factor ts. It allows an extra scaling on the					
COMMAND QUALIFIERS	None.					
EVALABLES						

EXAMPLES

SHADOW> SHOW SCALE

The uniform scale factor is 1.00000000

The above scale factor is the default. It has not been changed with SET SCALE.

SHOW UNITS

Displays the current units in effect. Valid units are meters, feet, and inches.

FORMAT

SHOW UNITS

Command Qualifiers None.

Defaults None.

restrictions

None.

prompts

None.

command parameters

None.

DESCRIPTION

There are three different units in which antenna locations may be specified. This command displays the units currently in effect. The SET UNITS command changes the default units.

COMMAND QUALIFIERS

None.

EXAMPLES

SHADOW> SHOW UNITS

The current units are feet

SHOW WINDOW

Displays the current window parameters.

FORMAT	SHOW WINDOW					
	Command Qualifiers None.	Defaults None.				
restrictions	None.					
prompts command parameters	None.					
	None.					
DESCRIPTION The output can be windowed onto a smaller range of thet with any desired resolution. The parameters for this windowed established by the SET WINDOW command.						
COMMAND QUALIFIERS	None.					

EXAMPLES

SHADOW> SHOW WIND

The current range of theta in degrees is 0.0000000E+00 to 180.0000 with a resolution of 2.000000 degrees/pixel.

The current range of phi in degrees is 0.000000E+00 to 360.0000 with a resolution of 2.000000 degrees/pixel.

In this case, the window is set to its default range with a resolution of two degrees/pixel.

Chapter 6

Interpretation of the Output

The final product of the obscuration code, SHADOW, is a map of the projected shadow of a defined object onto the far zone sphere with its center at the antenna location. The map is composed of pixels with the size and range specified by the user. The obscuration code provides complete control over the parameters needed to define the map and provides a line printer output or a plottable file that can be used by an external plotting code. This chapter outlines the details of defining, obtaining, and interpreting the shadow map.

For this discussion, the far zone sphere can be viewed as being ironed out into a flat plane, that is, a Mercator's projection with the angle phi along the x axis and the angle theta along the y axis. Using the VF non-interactive command or the SET WINDOW interactive command, the user can choose starting angles, incremental step size which is the resolution of the map, and the total number of steps or pixels for both the theta and phi angles. This, of course, also dictates the stopping angles of the map which it computes. The default is for theta to vary from 0 to 180 degrees in steps of 2 degrees for a total of 91 pixels, and for phi to vary from 0 to 360 in steps of 2 for a total of 181 pixels. The interactive command SET WINDOW allows these parameters to be changed at any time during a session. It asks for the starting and stopping angle and the resolution which is the step size and it computes the number of pixels for each angle. These angles are defined with respect to the pattern coordinate system, which is specified by the first set of angles in the VF command or by the SET PATTERN command. The default is for the pattern coordinate system to be the same as the reference coordinate system.

As discussed in Chapter 2, the code computes the shadow by first projecting the objects border onto the far zone sphere and then filling in between the borders. A pixel is considered to be filled if the border at least passes through more than half the distance to the center of a pixel. It determines this by rounding the theta and phi angles defining the border to the nearest integer with respect to the resolution size of the pixel, which is the step size. This sometimes appears to produce a ragged border around the edges of the shadow if the border is very curved. Note that a straight edged plate projects a shadow that is curved in border. In addition, this is dependent on the coordinate system in which the shadow is viewed. Chapter 7 presents specific examples of these types of maps.

The shadow is represented by an ASCII character being placed in an array corresponding to the integerized theta and phi angles. A clear viewing point is left blank. The choice of the character that is placed in the pixel can be controlled by the user. The default is for an "X" to be used as a fill character. Interactivly this can be changed using the SET FILL

command. Noninteractivly, these are hard-wired into the source code.

For debugging purposes or so that the user can get a feel for which plates and cylinders are shadowing which regions of space a highlighting feature has been provided. The SET FILL/SEQUENTIAL command tags each plate and cylinder with its own uniquie fill character. The first plate starts with "A" and each succeeding plate is incremented up by one ASCII character. The first cylinder starts with "1" and each succeeding cylinder is incremented up by one ASCII character. Note that if there are a lot of plates and/or cylinders, the fill characters will eventually get into some of the more seldom used ASCII characters. Also note that in this mode of filling, the code superimposes the latest calculated shadow for a plate or cylinder on top of the shadow map. This means that the character in a pixel for a finished map will represent the last object that the code calculated a shadow for and not the object that is located closest to the observer.

In order to get around the ambiguous behavior of highlighting the plates and cylinders by order of processing rather than by location, the user can instead use the standard fill character for all plates and cylinders and highlight one particular specified object. The command SET FILL/PLATE = (number, character) or SET FILL/CYLINDER = (number, character) will highlight the chosen plate or cylinder against the regular fill character. The plate or cylinder options are mutually exclusive. It represents the shadow of the whole plate or cylinder that is tagged. A non interactive command has not been provided for these fill features. The user can change the fill characters and mode in the INIT subroutine.

The output that the user sees can come in three forms. The first type of output comes from an echo of the command set that is read from the input file on logical unit #5. The output is sent to logical unit #6, which is normally assigned to a default file type of .LIS on a VAX in the interactive mode. An ASCII file of the shadow map is written to logical unit #7, which is normally assigned to a default file type of .PRT on a VAX. A binary file of the shadow map that can be used to transfer information to another code to plot the map is sent to logical unit #10, which is normally assigned to a default file type of .PLT on a VAX.

In the interactive mode, the input set can be opened using the SET OUTPUT command. The output files can be opened and closed using the SET OUTPUT /ECHOING, /PRINTABLE, /PLOTTABLE commands, respectively. In the non-interactive mode, they can be controlled by using system commands, such as ASSIGN on the VAX. In the interactive mode, the output files should generally be set first, so that the code will have the desired information as to where to sent the echo back information. In addition, once the code is run and it is desired to see the results, it is possible to print or plot the results using the SPAWN ("\$") command. The files that are desired to be printed or plotted, however, must be closed first, that is, the SET OUTPUT command should be given again reassigning the files to another name, a null device, or the printing device. This will close the files and allow them to be accessed. Of course, it is important to remember to reopen them after the user is finished and wants to run more results. Presently, the echo, printable, and plottable map files will accumulate information until they are closed.

Generally, the code will be used to produce plottable files of the shadow maps with the printable file being used for debug purposes. Plotted maps are small and nicer to look at. Unfortunately, graphical routines are presently system dependent. A plotting code for a NCAR [5], has been provided, however, in Chapter 13. This is one example of how the

data of the shadow map can be plotted. Examples of both the printed and plotted maps are illustrated in the examples of Chapter 7. It should be noted that due to the limited amount of space across the width of a line printer, a printed map will be broken up into widths that will fit onto the width of the paper if it is too wide. The map will come out in as many strips as necessary to produce the whole map. Plotted maps should not have this problem since the individual pixels can be graphed very close together.

Chapter 7

Examples

The following examples are used to illustrate the various features of the SHADOW computer code. Each example is designed to show how a set of non-interactive and interactive commands can be put together to solve a problem. The beginner can use the examples in this chapter to learn more about the code. In addition, these examples can be used to ensure that the code is operating correctly on your system. These examples were run on a DEC VAX 11/780 computer using version 4 of the VMS operating system.

The shadow maps shown here are presented mostly with the line printer output, since this is generally the most transportable. Plotted output would normally be preferred in a design situation. A few examples of this type of output are also given.

7.1 Example 1: A Plate

The first example is a four-cornered plate centered at the origin and situated in the X-Y plane. The antenna is located on the positive Z axis. It was generated with the following input files and commands. The commands were:

```
$ RUN SHADOW
SHADOW> SET OUT PLAEX1/NOPLOT/PRINT
SHADOW> SET INP PLAEX
SHADOW> SET UNI METERS
SHADOW> SET WIND
        90. 180
        1.0
        0., 360
        5.
SHADOW> SET ANT
SHADOW> 0,0,8
SHADOW> SHADOW
SHADOW> EXIT
   The input set defining the plate was the following:
CM:
      SIMPLE PLATE TEST SET
CE:
      RCS INPUT SET
UN:
1
PG: THE PLATE IS 400 SQUARE-METERS.

7.2 Example 2: A Different Plate

This example is another four-cornered plate, but this time the antenna is located at the origin, and the plate is centered along the positive Y axis and is normal to it.

The commands were:

```
$ RUN SHADOW
SHADOW> SET OUT PLAEX2/NOPLOT/PRINT
SHADOW> SET INP PLAEX2
SHADOW> SET UNI METERS
SHADOW> SET WIND

O, 180
2.0
O., 180
5.
SHADOW> SET ANT
O,O,O
SHADOW> SHADOW
SHADOW> EXIT
$ EXIT
```

The input set defining the plate was the following:

```
CM: SIMPLE PLATE TEST SET
CE: RCS INPUT SET
UN:

1
PG: THE PLATE IS 400 SQUARE-METERS.
4 0
-10.0, 8, +10.0
-10.0, 8, -10.0
+10.0, 8, -10.0
+10.0, 8, +10.0
XQ:
EN:
```

The output generated by the code was the following:

```
ANTENNA (RCS) = ( 0.0000, 0.0000, 0.0000 ) IN METERS
                             INPUT SET: USER1: [RJM.NAS.MAN] PLAEX2.INP;2
                        TRETA (DECREES)
                     80.00
                         100.00
                                  140.00
                                       160.00
                                            180.03

               170.00
175.00
180.00
```

7.3 Example 3: The First Plate Revisited

The current example is deceptive. Both the input geometry and the source location are identical with the first plate example, but the obscuration output is identical to the second example! A closer of the input sets reveals the two examples are really the same geometry, but defined in different orientations with respect to the Reference Coordinate System. The third example takes advantage of this fact and uses the SET PATTERN_CUT command to reorient the coordinate system of the antenna. The result is that while the geometry is defined the same as the first example, the output resembles the second example. The commands to generate the example were:

```
$ RUN SHADOW
SHADOW> SET OUT PLAEX3/NOPLOT/PRINT
SHADOW> SET INP PLAEX
SHADOW> SET UNI METERS
SHADOW> SET WIND
        0,180
        2.0
        0.,180
        5.
SHADOW> SET ANT
        0,0,8
SHADOW> SET PATT
        90., +90., 90., 0.
SHADOW> SHADOW
SHADOW> EXIT
$ EXIT
   The input set defining the plate was the same one used in example one. It is:
CM:
      SIMPLE PLATE TEST SET
      RCS INPUT SET
CE:
UN:
1
PG: THE PLATE IS 400 SQUARE-METERS.
4 0

```

7.4 Example 4: A Non-Interactive Version of Example 1

This example illustrates an input set for non-interactive use of the code. The main program has been changed to the non-interactive version and non-interactive subroutines were not linked into the code. The input set is the same as Example 1, except that the source and window have been define using the SG and VF commands, respectively. Note that these commands can also be used in the interactive mode also to hard wire the antenna location and window as a default case. The output is not shown here because it is identical to that of Example 1.

The input set defining the plate is the following:

```
CM:
      SIMPLE PLATE TEST SET
CE:
      RCS INPUT SET
UN:
1
PG: THE PLATE IS 400 SQUARE-METERS.
4 0
-10.0, +10.0, 0.0
-10.0, -10.0, 0.0

7.5 Example 5: An Elliptic Cylinder

This example is consists of one elliptic cylinder centered on the origin with its axis directed along the Y axis. Three different source locations are presented with this single example.

The commands were:

```
$ RUN SHADOW
SHADOW> SET OUT CYLEX1/NOPLOT/PRINT
SHADOW> SET INP CYLEX1
SHADOW> SET UNI METERS
SHADOW> SET WIND
130,180
0.5555556
0.,360
5.
! An overhead view of the cylinder, which is centered on the origin,
! with radii of 1 and 1, with a a length of 1 meter.
SHADOW> SET ANT
0.0.4
SHADOW> SHADOW
! A broadside look at the cylinder.
SHADOW> SET WIND
45,135
1.0
220.,310
1.25
SHADOW> SET ANT
0.4.0
SHADOV> SHADOV
! Now a look at the same geometry along the axis of the cylinder.
SHADOW> SET ANT
4,0,0
SHADOW> SET WIND
45.135
1.0
130.,220
1.25
SHADOW> SHADOW
SHADOV> EXIT
$ EXIT
   The input set defining the plate was the following:
      SIMPLE AIRCRAFT
CM:
      RCS INPUT SET

7.6 Example 6: Two Elliptic Cylinders

This example is consists of two elliptic cylinders equidistant from the origin with axes coincident and directed along the Y axis. Three different source locations are presented with this single example.

The commands were:

```
$ RUN SHADOW
SHADOW> SET OUT CYLEX2/NOPLOT/PRINT
SHADOW> SET INP CYLEX2
SHADOW> SET UNI METERS
SHADOW> SET WIND
130,180
0.5555556
0.,360
Б.
! An overhead view of the 2 cylinders with radii of 1 and 1,
! with a length of 1 meter each.
SHADOW> SET FILL /CYL=1
SHADOW> SET ANT
0,0,4
SHADOW> SHADOW
SHADOW> SET WIND
45,135
1.0
220.,310
1.25
SHADOW> SET ANT

7.7 Example 7: A Space Station Model

This example uses a space station, shown in Figure 7.1, that has been provided by NASA, Langley. The computer model is illustrated in Figure 7.2. It is an demonstrates how to use the windowing and highlighting commands (SET FILL) to effectively show obscuration.

The commands were:

```
$ RUN SHADOW
SHADOW> SET OUT ANSS1 /PRINT/NOECHO
SHADOW> SET INP AN5S1
SHADOW> SET UNI FEET
SHADOW> SET WIND
0,180
2.0
20.,290
2.5
! Display ONLY plate 6.
SHADOW> SET FILL " " /PLATE=6
SHADOW> SET ANT
       25, 15, 256.5
SHADOW> SHADOW
! Now make plate 6 stand out from the crowd.
SHADOW> SET FILL "!" /PLATE=(6,$)
SHADOW> SET ANT
       25, 15, 256.5
SHADOW> SHADOW
$ EXIT
   The input set defining the plate was the following:
CM: *********OBSCURATION********

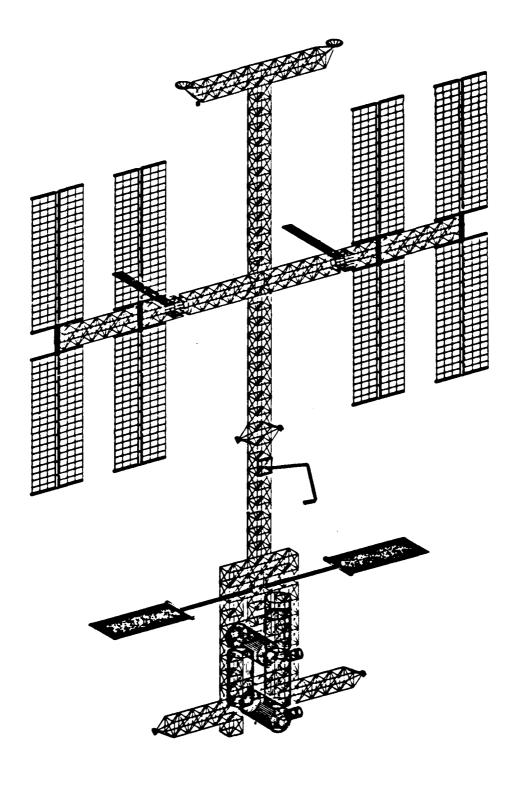

Figure 7.1: Illustration of the Space Station

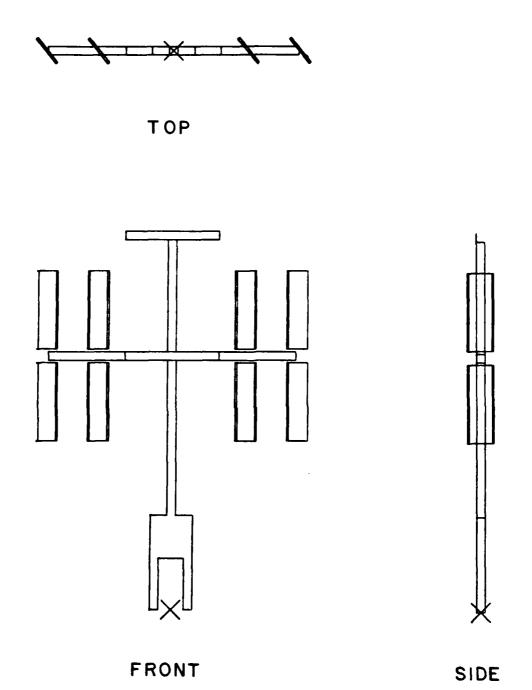

Figure 7.2: Three-axis view of the Space Station as modeled by the input set.

7.8 Example 8: Another Look at the Space Station

This example presents a full view of the space station in the previous, except that the output is generated with the NCAR graphics interface. The non-interactive input is the same. The standard fill character procedure is used and a complete window is displayed with two degree resolution in theta and phi. The NCAR plot has been obtained using the plotting code in Chapter 13. The shadow map produced is shown in Figure 7.3

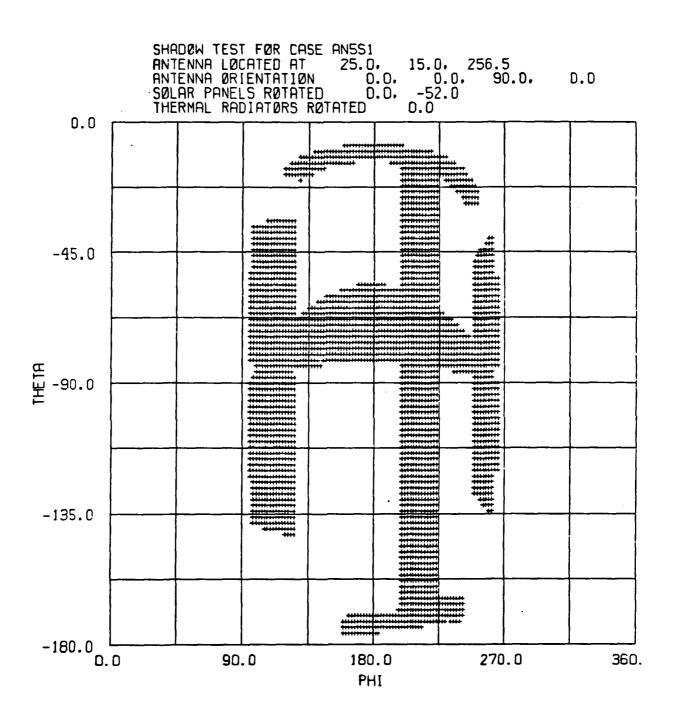

Figure 7.3: NCAR plot showing the shadow map of the space station model.

Part II

Code Manual

Chapter 8

Introduction

The obscuration code SHADOW, is designed to produce a projected shadow map onto the far zone radiation sphere of an antenna in a complex environment. The map is efficiently calculated by directly tracing the outer boundaries of the multisided flat plates and composite cone frustum cylinders onto theta – phi space and then filling between the boundaries along raster lines. The code has been developed to be interactively run on a DEC VAX computer. It can, also, be run non-iteractively on any other computer by simply substituting the small main program and leaving out the interactive subroutines.

Part I of this manual is a user's guide which treats the code from the users standpoint without much particular details about the coding. Part II, given here, is intended to give some details about the internal workings of the code. It gives more specific information about the coding itself. It is of importance primarily for people implementing the code on a new system, for debugging errors, or for making changes in how the code operates. An overview of how the code is organized is given in Chapter 9. A listing of the code is given in Chapter 10. It is broken up into three parts for the non-interactive, FORTRAN 77 subroutines and into the interactive VAX dependent subroutines. The implementation of the code on a VAX is given in Chapter 11 and a brief description of implementing the code on a non-VAX computer is given in Chapter 12. A listing of an NCAR plotting code for the shadow map is given in Chapter 13.

Chapter 9

Code Organization

The obscuration code SHADOW is designed to produce a projected shadow map onto the far zone radiation sphere of an antenna in a complex environment. The map is efficiently calculated by directly tracing the outer boundaries of the multisided flat plates and composite cone frustum cylinders onto theta – phi space and then filling between the boundaries along raster lines.

The code has been developed with efficiency and ease of use as primary considerations. Often with other similar codes the engineer is not part of a tight interactive design loop. In order to facilitate this capability, while maintaining necessary transportability, the code has been split into two versions so that it can be run in two different modes, interactively or non-interactively depending on the computer being used. In both versions the flow of program control is basically the same. The main program either accepts interactive commands from the terminal and acts on those commands, or reads a different set of non-interactive commands from the input file and processes those. In both cases, the main program loops on input commands and calls appropriate subroutines for the creation and output of the shadow map.

The map creation is broken down into separate phases for each class of geometry being processed. Plates and elliptic cylinders are the two phases currently implemented. Each processing phase works by projecting each member of each class of geometry onto the far-zone sphere. The code implements the shadow map by mapping the far zone sphere in theta-phi space into a rectangular character array. The size of the array and hence the angular resolution of the resulting map is determined by the user at run time. After a member is projected, the far-zone grid (array) is processed in a raster-scan fashion to implement an area fill for the member. In this way every geometric entity is processed and included in the array. After all items of all classes have been processed, the output routines format and display/dump the resulting map. The main program then readies itself to execute yet another command or commands.

The source code is also organized into two groups of files depending upon the desired mode of operation. The code is organized this way so that minimum source modification is necessary in order to run in either interactive (in the case of a VAX computer) or non-interactive modes. The chapter on Non-VAX implementation describes the conversion of the source to non-interactive mode in detail.

Since the map computation and display routines are identical for both modes of operation, the transportability of generated results depends on the numerical behavior of the

target machine an not on implementational differences between the interactive and non-interactive versions.

Chapter 10

Listings of the Code

This chapter describes the operation of the routines and functions used by the program. Each listing is presented in alphabetical order and is preceded where appropriate by a short explanation of methods used.

10.1 VAX/VMS Subroutines

The following routines are for the interactive implementations of the code. They are used in conjunction with the routines in this chapter that are common to both versions.

MAIN PROGRAM

This is the main routine for the interactive versions of the program. It calls a one-time initalization routine and then executes commands until finished. There is another slightly different main program for the non-interactive code.

SUBROUTINE INTRAC

This is the interactive commands subroutine called by the main routine. It fields commands typed by the user and executes the appropriate service routines. Also listed here are two I/O function subprograms which are indirectly invoked by INTRAC. They are called GET_INPUT and PUT_OUTPUT.

```

0013
        CIII
        C!!! THIS IS A PORTION OF THE MAIN PROGRAM OF THE NEC-BSC
0014
        C!!! IT READS IN THE INPUT AND PASSES THE GEOMETRY INFORMATION
0015
0016
        C!!! TO THE SHADOW CALCULATION PART OF THIS OBSCURATION CODE.
0017
        C!!! IT READS LOCATIONS OF SOURCES A NUMBER OF FINITE
0018
        C!!! PLATES AND/OR A SET OF FINITE
0019
        C!!! ELLIPTIC CYLINDERS AND CONE FRUSTUM SECTIONS.
0020
        C!!! THE PLATES ARE DEFINED
0021
        C!!! BY THEIR CORNER LOCATIONS. THEY CAN BE PERFECTLY
        C!!! CONDUCTING, MULTI LAYERED DIELECTRIC SLABS, OR COATED
0022
        C!!! METAL PLATES. AN INFINITE GROUND PLANE CAN ALSO BE
0023
        C!!! ADDED. THE CYLINDERS ARE DEFINED BY THEIR ORIGIN,
0024
        C!!! AXES DIRECTIONS, AND BY THE RADIUS ON THEIR MAJOR
0025
0026
        C!!! AND MINOR AXES AND THE ENDCAPS AND FRUSTUM RIMS ARE DEFINED BY
0027
        C111
             THEIR POSITION ON THE CYLINDER AXIS AND THE ANGLE
        C!!! OF THEIR SURFACES WITH THE CYLINDER AXIS IN THE X-Z
0028
0029
        C!!! CYLINDER PLANE. THE CYLINDERS MUST BE PERFECTLY
0030
        C!!! CONDUCTING. AS DIMENSIONED, IT CAN HANDLE 75 PLATES
        C!!! WITH A MAXIMUM OF 12 CORNERS PER PLATE, WITH 5 LAYERS
0031
0032
             OF DIELECTRIC AND 6 CYLINDERS, WITH 10 RIMS
        CIII
        C!!! ALSO 30 TRANSMITTING
0033
0034
        C!!! ELEMENTS AND 30 RECEIVING ELEMENTS CAN BE INPUT.
0035
        CITI NOTE THAT THE LIMITS ON THE NUMBER OF PLATES,
0036
        C111
             CORNERS, LAYERS, CYLINDERS, SOURCES, AND RECEIVERS
0037
        C!!! ARE ONLY DUE TO THE SIZE OF THE ARRAYS.
0038
        C!!! THE LINEAR DIMENSIONS ARE INPUT IN METERS UNLESS
0039
        Citi Specified Otherwise. The Angular Dimensions
        C!!! ARE IN DEGREES.
0040
0041
        CIII
             NOTE THAT COMMENTS ARE INDICATED IN DIFFERENT FORMS:
0042
        CIII

10.4 Non-FORTRAN VAX/VMS source files

This section contains listings of the source files used by the interactive code which are not written in fortran. They are used by the interactive interface and are needed only by the VMS utilities.

CDU Source file

This file is the source input for the Command Language Definiton Utility (CDU) which defines the available interactive commands.

```

Chapter 11

VAX Implementation

This chapter describes the VAX/VMS implementation of the shadow program. The program has been split into two parts which are not used together. When the computer environment is the VAX/VMS operating system, then the more flexible interactive mode described in this chapter should be used. Assuming that the required files have been properly restored from the distribution medium, there are procedures provided to accomplish assembly of the code with minimum user effort.

11.1 Assembling the Code

On a VAX/VMS computer system, the following files are required to build and use the code. Both the interactive and non-interactive versions of the code can be run in any of the standard VMS ways, that is interactively, in a batch queue mode, or in a DCL subprocess. The actual building of the program takes place by invoking the procedure SHABLD.COM. The resulting executable file SHADOW.EXE can then be run with the RUN command.

- SHABLD.COM A DCL command procedure to compile and link the files. This is the main assembly command file.
- SHACMD.CLD A VMS Command Language Definition file used define the interactive commands available.
- SHACOM.FOR The one include file for the code common blocks. The other include statements that appear in the code reference system libraries.
- SHADNI.FOR This contains the alternate code that is to be used when a non-interactive code is desired.
- SHADNW.FOR This contains code that is very much dependent on the facilities of VMS and has been seperated as such. It is an essential part of the interactive program.
- SHADOW.FOR This is the main body of the code and is common to both interactive and non-interactive versions. It is standard FORTRAN-77.
- SHADOW.HLB This is the VMS-format help library containing descriptions and examples of interactive commands.

- SHADOW.KPD This is an initalization file used by the interactive program to equivalence certain functions to keys of the user's choice.
- SHAPLT.COM This is a DCL command procedure invoking the NCAR graphics plotting software.
- SHAPLT.FOR This is the FORTRAN program which reads the output produced by the code and calls appropriate NCAR routines to make a plot.
- LABEL.DAT This file is read by the SHAPLT program in order to label the NCAR plots.

11.2 Running the Code

In order to run the code on VMS, the executable file created by the SHABLD procedure is necessary. The program is then run with the dcl RUN command.

A typical interactive session with the program might consist of the following elements in their approximate order of execution.

- OUTPUT FILES Establish a set of output files with the SET OUTPUT command. The output files are of three types. Using the qualifiers of the SET OUTPUT command, any desired combination of output files may be generated.
- PROCESS AN INPUT Issue a SET INPUT command which reads the geometry from the specified file. In order for the program to process input sets, this command must be issued prior to any mapping commands. This command is usually executed once per session.
- **DEFINE A WINDOW** Using the SET WINDOW command, establish the angular range of interest. When the program begins, the size of the window is set to the full angular extent of the far-zone sphere. By specifying a smaller angular range, the user examines portions of the geometry in greater detail.
- **DEFINE A SOURCE** With the SET ANTENNA command, establish the location of the source. This command is one of the more frequently entered commands. It applies units and coordinate transformations that apply from the set units and set coordinates command.
- HIGHLIGHT ITEMS With the SET FILL command, the user may optionally cause parts of the geometry to be marked. This very usefull command may be executed at any time before a SHADOW command.
- GENERATE A MAP Cause the generation of a shadow map by issuing a SHADOW command. The shadow command is used after the user has set all desired parameters including the window and the antenna location. Without executing this command, the code does not calculate any shadowing.
- REPEAT ANY OF THE ABOVE Perform one or more of the above actions repeatedly to obtain several maps. Most of the commands above may be executed in any order provided that the SHADOW command is executed last.

EXIT Terminate the shadow session with an EXIT command. An acceptable alternate mode of exit is eof, or control-Z.

In order to make life easier by reducing the number of keystrokes required to enter interactive commands, a facility is provided with which the user may associate whole command strings with a single key. When the shadow program begins executing, it loads a set of predefined key definitions from a file. The user may edit this file to customize the keypad definitions to his/her liking. Since the file is loaded automaticly, the only restriction on its use is that it must exist in the current process default directory and must be accessible at run time. The details about these interface routines and what they do may be found in the VAX/VMS Runtime Library Reference Manual.

11.3 Modifying the code

Modifications to the source code by the user can be performed, but of course the outcome cannot be predicted beforehand. One predictable user modification is changing the program's PARAMETER statements in the include file SHACOM.FOR. This would be necessary (and sufficient) to allow the program to deal with a greater number of plates or to construct a shadow map with greater resolution than the current maximum.

Chapter 12

Non-VAX Implementation

This chapter discusses how to implement the code on a different computer than a VAX. The obscuration code, SHADOW, has been separated into two main parts. The FORTRAN 77 part, is not VAX dependent and is contained in a file called SHADOW.FOR. Most of the rest of the files are VAX dependent and are used mostly for interactive features. Although, it is possible that other types of machines will have similar routines that will allow interactive manipulation, it is not possible here to suggest how this may be accomplished. It is assumed that the easiest way to use SHADOW on a non-VAX would be to run it in a non-interactive mode.

The main program in the default version of the file SHADOW.FOR is designed to be used with the non-FORTRAN 77 interactive version. A file called SHADNI.FOR contains a main program designed to be used in a non-interactive mode. It is listed in section 10.2. The main programs can be easily exchanged.

Note that the only other part of the code is this part that is non-FORTRAN 77 is the INCLUDE statement. This has been retained because many computer systems support this statement. It is used to include the lines of code in the named file in the spot that it is called as if the lines had been in that spot. It provides a powerful means of putting commonly defined parameters used throughout the code in one place. In this case, it is used to include the file SHACOM.FOR which contains COMMON blocks and PARAMETER statements that define the dimensions of arrays that store the geometry. If it is desired to increase the number of plates, edges per plate, cylinders, or rims per cylinder, etc; they can be changed in one spot. Please see the listing for this file elsewhere in this manual. The INCLUDE statement can be easily removed by hardwiring the contents of the file SHACOM.FOR into the text at the main program and the subroutines ABSCIN, CAPINT, CYLINT, CYLROT, DOCYLS, DOCYL, DOPLAS, DOPLA, GEOM, INITGF, PLAINT, SCAN, SCANC, SPANC, and WRTOUT.

The code can now be compiled, linked, and run. The user communicates with the code through the non-interactive commands. This allows almost the same capability. The only information that does not have a command to change its behavior is the fill options and the input and output file names. The fill options can be accessed through the main program. The listing below has comment lines referring to the place that the fill operations may be changed.

The input and output files can be named using assignments to the logical unit numbers for the given operation. The input file is read on logical unit #5. The echo file is written

on logical unit #6. The printable shadow map is written on logical unit #7. The plottable shadow map is written on logical unit #10. On a VAX the ASSIGN VMS command would be used.

Note that the user can specify more than one source. The non-interactive operation will run a shadow map for each source individually. The receiver will not be counted. If the user wants to look at the shadow map for a receiver, they should be treated in this code as if they are a transmitter (source).

Chapter 13

NCAR Plot Program

The shadow map can be plotted using graphical means. The SHADOW code will write a unformatted file that can be used for interfacing to special purpose plotting programs. It writes this file on logical unit #10. In the interactive mode the file name is specified by using the SET OUTPUT commands /PLOTTABLE option. In the non-interactive mode the file name is specified using an assign statement.

There are many ways to plot the resulting shadow map. Presently, there is little standardization between system for plotting. This may change with the advent of GKS, but for now, it can not be assumed that different organizations have compatible plotting capabilities. This chapter suggests one possible means to plot the output. It uses the National Center for Atmospherics Research (NCAR) graphics package [5]. It has been tried on The Ohio State University ElectroScience Laboratory's computer system and NASA Langley Research Center's computer system, both VAX 11/780s, with almost the same results. It is still not possible, however, to assume that it will run everywhere the same way.

The program is listed for the convenience of possible users, knowing that some conversion may be necessary. The code is written in basic NCAR subroutine calls. Consult your local system information on how to link to your systems NCAR graphics subroutines. In addition, it is not written completely in standard FORTRAN 77. There are a few VAX extensions used, such as some of the options in the OPEN subroutine and some comment lines use the non-standard exclamation point. These changes will be minor.

Note that the plot of the shadow map will have grid lines. There is another option given for a map without grid lines. This can be used by commenting out the call to subroutine GRIDL, and uncommenting the call to subroutine PERIML.

The file name containing the maps to be plotted are placed in the first line of a file named LABEL.DAT. The LABEL.DAT file also contains the header information to be place at the top of the plot for future identification and reference. The code will loop through the specified shadow map file until all the shadow map contained in the file are plotted. A sample version of a LABEL.DAT file is given after the code listing. It shows a shadow map being read off of file FOR010.DAT which contains two shadow maps.

Listing of code to plot shadow map using NCAR:
